This document is being reorganized. Expect redundancy, inconsistencies, disorganized presentation ...

## 1 Motivation

There is a wide range of interesting processes in robotics, control, economics, that can be described as a differential equations with non-deterministic dynamics. Suppose the original processes is described by the following differential equation

$$
\begin{equation*}
\frac{d X_{t}}{d t}=a\left(X_{t}\right) \tag{1}
\end{equation*}
$$

with initial condition $X_{0}$, which could be random. We wish to construct a mathematical model of how the may behave in the presence of noise. We wish for this noise source to be stationary and independent of the current state of the system. We also want for the resulting paths to be continuous.

As it turns out building such a model is tricky. An elegant mathematical solution to this problem may be found by considering a discrete time versions of the process and then taking limits in some meaningful way. Let $\pi=\left\{0=t_{0} \leq t_{1} \cdots \leq t_{n}=t\right\}$ be a partition of the interval $[0, t]$. Let $\Delta^{\pi} t_{k}=t_{k+1}-t_{k}$. For each partition $\pi$ we can construct a continuous time process $X^{\pi}$ defined as follows

$$
\begin{align*}
& X_{t_{0}}^{\pi}=X_{0}  \tag{2}\\
& X_{t_{k+1}}^{\pi}=X_{t_{k}}^{\pi}+a\left(X_{t_{k}}^{\pi}\right) \Delta^{\pi} t_{k}+c\left(X_{t_{k}}^{\pi}\right)\left(N_{t_{k+1}}-N_{t_{k}}\right) \tag{3}
\end{align*}
$$

where $N$ is a noise process whose properties remain to be determined and $b$ is a function that allows us to have the amount of noise be a function of time and of the state. To make the process be continuous in time, we make it piecewise constant between the intervals defined by the partition, i.e.

$$
\begin{equation*}
X_{t}^{\pi}=X_{t_{k}}^{\pi} \text { for } t \in\left[t_{k}, t_{k+1}\right) \tag{4}
\end{equation*}
$$

We want for the noise $N_{t}$ to be continuous and for the increments $N_{t_{k+1}}-N_{t_{k}}$ to have zero mean, and to be independently and identically distributed. It turns out that the only noise source that satisfies these requirements is Brownian motion. Thus we get

$$
\begin{equation*}
X_{t}^{\pi}=X_{0}+\sum_{k=0}^{n-1} a\left(X_{t_{k}}^{\pi}\right) \Delta t_{k}+\sum_{k=0}^{n-1} c\left(X_{t_{k}}^{\pi}\right) \Delta B_{k} \tag{5}
\end{equation*}
$$

where $\Delta t_{k}=t_{k+1}-t_{k}$, and $\Delta B_{k}=B_{t_{k+1}}-B_{t_{k}}$ where $B$ is Brownian Motion. Let $\|\pi\|=\max \left\{\Delta t_{k}\right\}$ be the norm of the partition $\pi$. It can be shown that as $\pi \rightarrow 0$ the $X^{\pi}$ processes converge in probability to a stochastic process $X$. It follows that

$$
\begin{equation*}
\lim _{\|\pi\| \rightarrow 0} \sum_{k=0}^{n-1} a\left(X_{t_{k}}^{\pi}\right) \Delta_{k}=\int_{0}^{t} a\left(X_{s}\right) d s \tag{6}
\end{equation*}
$$

and that

$$
\begin{equation*}
\sum_{k=0}^{n-1} c\left(X_{t_{k}}^{\pi}\right) \Delta B_{k} \tag{7}
\end{equation*}
$$

converges to a process $I_{t}$

$$
\begin{equation*}
I_{t}=\lim _{\|\pi\| \rightarrow 0} \sum_{k=0}^{n-1} c\left(X_{t_{k}}^{\pi}\right) \Delta B_{k} \tag{8}
\end{equation*}
$$

Note $I_{t}$ looks like an integral where the integrand is a random variable $c\left(X_{s}\right)$ and the integrator $\Delta B_{k}$ is also a random variable. As we will see later, $I_{t}$ turns out to be an Ito Stochastic Integral. We can now express the limit process $X$ as a process satisfying the following equation

$$
\begin{equation*}
X_{t}=X_{0}+\int_{0}^{t} a\left(X_{s}\right) d s+I_{t} \tag{9}
\end{equation*}
$$

Sketch of Proof of Convergence: Construct a sequence of partitions $\pi_{1}, \pi_{2}, \cdots$ each one being a refinement of the previous one. Show that the corresponding $X_{t}^{\pi-i}$ form a Cauchy sequence in $L_{2}$ and therefore converge to a limit. Call that process X.

In order to get a better understanding of the limit process $X$ there are two things we need to do: (1) To study the properties of Brownian motion and (2) to study the properties of the Ito stochastic integral.

## 2 Standard Brownian motion

By Brownian motion we refer to a mathematical model of the random movement of particles suspended in a fluid. This type of motion was named after Robert Brown that observed it in pollens of grains in water. The processes was described mathematically by Norbert Wiener, and is is thus also called a Wiener Processes. Mathematically a standard Brownian motion (or Wiener Process) is defined by the following properties:

1. The process starts at zero with probability 1 , i.e., $P\left(B_{0}=0\right)=1$
2. The probability that a randomly generated Brownian path be continuous is 1 .
3. The path increments are independent Gaussian, zero mean, with variance equal to the temporal extension of the increment. Specifically for $0 \leq s_{1} \leq$ $t_{1} \leq s_{2}, \leq t_{2}$

$$
\begin{align*}
& B_{t_{1}}-B_{s_{1}} \sim \mathcal{N}\left(0, s_{1}-t_{1}\right)  \tag{10}\\
& B_{t_{2}}-B_{s_{2}} \sim \mathcal{N}\left(0, s_{2}-t_{2}\right) \tag{11}
\end{align*}
$$

and $B_{t_{2}}-B_{s_{2}}$ is independent of $B_{t_{1}}-B_{s_{1}}$.

Wiener showed that such a process exists, i.e., there is a stochastic process that does not violate the axioms of probability theory and that satisfies the 3 aforementioned properties.

### 2.1 Properties of Brownian Motion

### 2.1.1 Statistics

From the properties of Gaussian random variables,

$$
\begin{align*}
& \mathbb{E}\left(B_{t}-B_{s}\right)=0  \tag{12}\\
& \operatorname{Var}\left(B_{t}-B_{s}\right)=\mathbb{E}\left[\left(B_{t}-B_{s}\right)^{2}\right]=t-s  \tag{13}\\
& \mathbb{E}\left(\left(B_{t}-B_{s}\right)^{4}\right]=3(t-s)  \tag{14}\\
& \operatorname{Var}\left[\left(B_{t}-B_{s}\right)^{2}\right]=\mathbb{E}\left[\left(B_{t}-B_{s}\right)^{4}\right]-\mathbb{E}\left[\left(B_{t}-B_{s}\right)^{2}\right]^{2}=2(t-s)^{2}  \tag{15}\\
& \operatorname{Cov}\left(B_{s}, B_{t}\right)=s, \text { for } t>s  \tag{16}\\
& \operatorname{Corr}\left(B_{s}, B_{t}\right)=\sqrt{\frac{s}{t}}, \quad \text { for } t>s \tag{17}
\end{align*}
$$

Proof: For the variance of $\left(B_{t}-B_{s}\right)^{2}$ we used the that for a standard random variable $Z$

$$
\begin{equation*}
\mathbb{E}\left(Z^{4}\right)=3 \tag{18}
\end{equation*}
$$

Note

$$
\begin{equation*}
\operatorname{Var}\left(B_{T}\right)=\operatorname{Var}\left(B_{T}-B_{0}\right)=T \tag{19}
\end{equation*}
$$

since $P\left(B_{0}=0\right)$ and for all $\Delta_{t} \geq 0$

$$
\begin{equation*}
\operatorname{Var}\left(B_{t+\Delta_{t}}-B_{t}\right)=\Delta_{t} \tag{20}
\end{equation*}
$$

Moreover,

$$
\begin{align*}
\operatorname{Cov}\left(B_{s}, B_{t}\right) & =\operatorname{Cov}\left(B_{s}, B_{s}+\left(B_{t}-B_{s}\right)\right)=\operatorname{Cov}\left(B_{s}, B_{s}\right)+\operatorname{Cov}\left(B_{s},\left(B_{t}-B_{s}\right)\right) \\
& =\operatorname{Var}\left(B_{s}\right)=s \tag{21}
\end{align*}
$$

since $B_{s}$ and $B_{t}-B_{s}$ are uncorrelated.

### 2.1.2 Distributional Properties

Let $B$ represent a standard Brownian motion (SBM) process.

- Self-similarity:

For any $c \neq 0, X_{t}=\frac{1}{\sqrt{c}} B_{c t}$ is SBM.
We can use this property to simulate SBM in any given interval $[0, \mathrm{~T}]$ if we know how to simulate in the interval $[0,1]$ :
If $B$ is SBM in $[0,1], c=\frac{1}{T} \quad$ then $X_{t}=\sqrt{T} B_{\frac{1}{T} t}$ is SBM in $[0, \mathrm{~T}]$.

- Time Inversion: $X_{t}=t B_{\frac{1}{t}}$ is SBM
- Time Reversal: $X_{t}=B_{T}-B_{T-t}$ is SBM in the interval $[0, T]$
- Symmetry: $X_{t}=-B_{t}$ is SBM

### 2.1.3 Pathwise Properties

- Brownian motion sample paths are non-differentiable with probability 1

This is the basic why we need to develop a generalization of ordinary calculus to handle stochastic differential equations. If we were to define such equations simply as

$$
\begin{equation*}
\frac{d X_{t}}{d t}=a\left(X_{t}\right)+c\left(X_{t}\right) \frac{d B_{t}}{d t} \tag{22}
\end{equation*}
$$

we would have the obvious problem that the derivative of Brownian motion does not exist.
Proof: Let $X$ be a real valued stochastic process. For a fixed $t$ let $\pi=\left\{0=t_{0} \leq\right.$ $\left.t_{1}, \cdots \leq t_{n}=t\right\}$ be a partition of the interval $[0, t]$. Let $\|\pi\|$ be the norm of the partition. The quadratic variation of $X$ at $t$ is a random variable represented as $<X, X>{ }_{t}^{2}$ and defined as follows

$$
\begin{equation*}
<X, X>_{t}^{2}=\lim _{\|\pi\| \rightarrow 0} \sum_{k=1}^{n}\left|X_{t_{k+1}}-X_{t_{k}}\right|^{2} \tag{23}
\end{equation*}
$$

We will show that the quadratic variation of SBM is larger than zero with probability one, and therefore the quadratic paths are not differentiable with probability 1.
Let $B$ be a Standard Brownian Motion. For a partition $\pi=\left\{0=t_{0} \leq t_{1}, \cdots \leq\right.$ $\left.t_{n}=t\right\}$ let $B_{k}^{\pi}$ be defined as follows

$$
\begin{equation*}
B_{k}^{\pi}=B_{t_{k}} \tag{24}
\end{equation*}
$$

Let

$$
\begin{equation*}
S^{\pi}=\sum_{k=1}^{n}\left(\Delta B_{k}^{\pi}\right)^{2} \tag{25}
\end{equation*}
$$

Note

$$
\begin{equation*}
\mathbb{E}\left(S^{\pi}\right)=\sum_{k=0}^{n-1} t_{k+1}-t_{k}=t \tag{26}
\end{equation*}
$$

and

$$
\begin{align*}
0 \leq \operatorname{Var}\left(S^{\pi}\right) & =\sum_{k=0}^{n-1} \operatorname{Var}\left[\left(\Delta B_{k}^{\pi}\right)^{2}\right] \\
& =2 \sum_{k=0}^{n-1}\left(t_{k+1}-t_{k}\right)^{2} \\
& \leq 2\|\pi\| \sum_{k=0}^{n-1}\left(t_{k+1}-t_{k}\right)=2\|\pi\| t \tag{27}
\end{align*}
$$

Thus

$$
\begin{equation*}
\lim _{\|\pi\| \rightarrow 0} \operatorname{Var}\left(S^{\pi}\right)=\lim _{\|\pi\| \rightarrow 0} \mathbb{E}\left[\left(\sum_{k=0}^{n-1}\left(\Delta B_{k}^{\pi}\right)^{2}-t\right)^{2}\right]=0 \tag{28}
\end{equation*}
$$

This shows mean square convergence, which implies convergence in probability, of $S^{\pi}$ to $t$. (I think) almost sure convergence can also be shown.

## Comments:

- If we were to define the stochastic integral $\int_{0}^{t}\left(d B_{s}\right)^{2}$ as

$$
\begin{equation*}
\int_{0}^{t}\left(d B_{s}\right)^{2}=\lim _{\|\pi\| \rightarrow 0} S^{\pi} \tag{29}
\end{equation*}
$$

Then

$$
\begin{equation*}
\int_{0}^{s}\left(d B_{s}\right)^{2}=\int_{0}^{t} d_{s}=t \tag{30}
\end{equation*}
$$

- If a path $X_{t}(\omega)$ were differentiable almost everywhere in the interval $[0, T]$ then

$$
\begin{align*}
& \left.<X, X>_{t}^{2}(\omega)\right) \leq \lim _{\Delta_{t} \rightarrow 0} \sum_{k=0}^{n-1}\left(\Delta_{t} X_{t_{k}}^{\prime}(\omega)\right)^{2}  \tag{31}\\
& =\left(\max _{t \in[0, T]} X_{t}^{\prime}(\omega)^{2}\right) \lim _{n \rightarrow \infty} \sum \Delta_{t}^{2}  \tag{32}\\
& =\left(\max _{t \in[0, T]} X_{t}^{\prime}(\omega)^{2}\right) \lim _{n \rightarrow \infty}(n)(T / n)^{2}=0 \tag{33}
\end{align*}
$$

where $X^{\prime}=d X / d t$. Since Brownian paths have non-zero quadratic variation with probability one, they are also non-differentiable with probability one.

### 2.2 Simulating Brownian Motion

Let $\pi=\left\{0=t_{0} \leq t_{1} \cdots \leq t_{n}=t\right\}$ be a partition of the interval $[0, t]$. Let $\left\{Z_{1}, \cdots, Z_{n}\right\}$; be i.i.d Gaussian random variables $\mathbb{E}\left(Z_{i}\right)=0 ; \operatorname{Var}\left(Z_{i}\right)=1$. Let the stochastic process $B^{\pi}$ as follows,

$$
\begin{align*}
& B_{t_{0}}^{\pi}=0  \tag{34}\\
& B_{t_{1}}^{\pi}=B_{t_{0}}^{\pi}+\sqrt{t_{1}-t_{0}} Z_{1}  \tag{35}\\
& \vdots  \tag{36}\\
& B_{t_{k}}^{\pi}=B_{t_{k-1}}^{\pi}+\sqrt{t_{k}-t_{k-1}} Z_{k} \tag{37}
\end{align*}
$$

Moreover,

$$
\begin{equation*}
B_{t}^{\pi}=B_{t_{k-1}}^{\pi} \quad \text { for } t \in\left[t_{k-1}, t_{k}\right) \tag{38}
\end{equation*}
$$

For each partition $\pi$ this defines a continuous time process. It can be shown that as $\|\pi\| \rightarrow 0$ the process $B^{\pi}$ converges in distribution to Standard Brownian Motion.

### 2.2.1 Exercise

Simulate Brownian motion and verify numerically the following properties

$$
\begin{align*}
& \mathbb{E}\left(B_{t}\right)=0  \tag{39}\\
& \operatorname{Var}\left(B_{t}\right)=t  \tag{40}\\
& \int_{0}^{t} d B_{s}^{2}=\int_{0}^{s} d s=t \tag{41}
\end{align*}
$$

## 3 The Ito Stochastic Integral

We want to give meaning to the expression

$$
\begin{equation*}
\int_{0}^{t} Y_{s} d B_{s} \tag{42}
\end{equation*}
$$

where $B$ is standard Brownian Motion and $Y$ is a process that does not anticipate the future of Brownian motion. For example, $Y_{t}=B_{t+2}$ would not be a valid
integrand. A random process $Y$ is simply a set of functions $f(t, \cdot)$ from an outcome space $\Omega$ to the real numbers, i.e for each $\omega \in \Omega$

$$
\begin{equation*}
Y_{t}(\omega)=f(t, \omega) \tag{43}
\end{equation*}
$$

We will first study the case in which $f$ is piece-wise constant. In such case there is a partition $\pi=\left\{0=t_{0} \leq t_{1} \cdots \leq t_{n}=t\right\}$ of the interval $[0, t]$ such that

$$
\begin{equation*}
f_{n}(t, \omega)=\sum_{k=0}^{n-1} C_{k}(\omega) \xi_{k}(t) \tag{44}
\end{equation*}
$$

where

$$
\xi_{k}(t)= \begin{cases}1 & \text { if } t \in\left[t_{k}, t_{k+1}\right)  \tag{45}\\ 0 & \text { else }\end{cases}
$$

where $C_{k}$ is a non-anticipatory random variable, i.e., a function of $X_{0}$ and the Brownian noise up to time $t_{k}$. For such a piece-wise constant process $Y_{t}(\omega)=$ $f_{n}(t, \omega)$ we define the stochastic integral as follows. For each outcome $\omega \in \Omega$

$$
\begin{equation*}
\int_{0}^{t} Y_{s}(\omega) d B_{s}(\omega)=\sum_{k=0}^{n-1} C_{k}(\omega)\left(B_{t_{k+1}}(\omega)-B_{t_{k}}(\omega)\right) \tag{46}
\end{equation*}
$$

More succinctly

$$
\begin{equation*}
\int_{0}^{t} Y_{s} d B_{s}=\sum_{k=0}^{n-1} C_{k}\left(B_{t_{k+1}}-B_{t_{k}}\right) \tag{47}
\end{equation*}
$$

This leads us to the more general definition of the Ito integral
Definition of the Ito Integral Let $f(t, \cdot)$ be a non-anticipatory function from an outcome space $\Omega$ to the real numbers. Let $\left\{f_{1}, f_{2}, \cdots\right\}$ be a sequence of elementary non-anticipatory functions such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \mathbb{E}\left[\int_{0}^{t}\left(f(s, \omega)-f_{n}(s, \omega)\right)^{2} d s\right]=0 \tag{48}
\end{equation*}
$$

Let the random process $Y$ be defined as follows: $Y_{t}(\omega)=f(t, \omega)$ Then the Ito integral

$$
\begin{equation*}
\int_{0}^{t} Y_{s} d B_{s} \tag{49}
\end{equation*}
$$

is a random variable defined as follows. For each outcome $\omega \in \Omega$

$$
\begin{equation*}
\int_{0}^{t} f(s, \omega) d B_{s}(\omega)=\lim _{n \rightarrow \infty} \int_{0}^{t} f_{n}(t, \omega) d B_{s}(\omega) \tag{50}
\end{equation*}
$$

where the limit is in $L_{2}(P)$. It can be shown that an approximating sequence $f_{1}, f_{2} \cdots$ satisfying (48) exists. Moreover the limit in (50) also exists and is independent of the choice of the approximating sequence.

Comment Strictly speaking we need for $f$ to be measurable, i.e., induce a proper random variable. We also need for $f(t, \cdot)$ to be $\mathcal{F}_{t}$ adapted. This basically means that $Y_{t}$ must be a function of $Y_{0}$ and the Brownian motion up to time $t$ It cannot be a function of future values of $B$. Moreover we need $\mathbb{E}\left[\int_{0}^{t} f(t, \cdot)^{2} d t\right] \leq \infty$.

### 3.1 Properties of the Ito Integral

- 

$$
\begin{equation*}
\mathbb{E}\left(I_{t}\right)=0 \tag{51}
\end{equation*}
$$

$$
\begin{equation*}
\operatorname{Var}\left(I_{t}\right)=\mathbb{E}\left(I_{t}^{2}\right)=\int_{0}^{t} \mathbb{E}\left(X_{s}^{2}\right) d s \tag{52}
\end{equation*}
$$

- 

$$
\begin{equation*}
\int_{0}^{t}\left(X_{s}+Y_{s}\right) d B_{s}=\int_{0}^{t} X_{s} d B_{s}+\int_{0}^{t} Y_{s} d B_{s} \tag{53}
\end{equation*}
$$

- 

$$
\begin{equation*}
\int_{0}^{T} X_{s} d B_{s}=\int_{0}^{t} X_{s} d B_{s}+\int_{t}^{T} X_{s} d B_{s} \text { for } t \in(0, T) \tag{54}
\end{equation*}
$$

- The Ito integral is a Martingale process

$$
\begin{equation*}
\mathbb{E}\left(I_{t} \mid \mathcal{F}_{s}\right)=I_{s} l \text { for all } t>s \tag{55}
\end{equation*}
$$

where $\mathbb{E}\left(I_{t} \mid \mathcal{F}_{s}\right)$ is the least squares prediction of $I_{t}$ based on all the information available up to time $s$.

## 4 Stochastic Differential Equations

In the introduction we defined a limit process $X$ which was the limit process of a dynamical system expressed as a differential equation plus Brownian noise perturbation in the system dynamics. The process was a solution to the following equation

$$
\begin{equation*}
X_{t}=X_{0}+\int_{0}^{t} a\left(X_{s}\right) d s+I_{t} \tag{56}
\end{equation*}
$$

where

$$
\begin{equation*}
I_{t}=\lim _{\|\pi\| \rightarrow 0} c\left(X_{t_{k}}^{\pi}\right) \Delta B_{k} \tag{57}
\end{equation*}
$$

It should now be clear that $I_{t}$ is in fact an Ito Stochastic Integral

$$
\begin{equation*}
I_{t}=\int_{0}^{t} c\left(X_{s}\right) d B_{s} \tag{58}
\end{equation*}
$$

and thus $X$ can be expressed as the solution of the following stochastic integral equation

$$
\begin{equation*}
X_{t}=X_{0}+\int_{0}^{t} a\left(X_{s}\right) d s+\int_{0}^{t} c\left(X_{s}\right) d B_{s} \tag{59}
\end{equation*}
$$

It is convenient to express the integral equation above using differential notation

$$
\begin{equation*}
d X_{t}=a\left(X_{t}\right) d t+c\left(X_{t}\right) d B_{t} \tag{60}
\end{equation*}
$$

with given initial condition $X_{0}$. We call this an Ito Stochastic Differential Equation (SDE). The differential notation is simply a pointer, and thus acquires its meaning from, the corresponding integral equation.

### 4.1 Second order differentials

The following rules are useful

$$
\begin{align*}
& \int_{0}^{t} X_{t}(d t)^{2}=0  \tag{61}\\
& \int_{0}^{t} X_{t} d B_{t} d t=0  \tag{62}\\
& \int_{0}^{t} X_{t} d B_{t} d W_{t}=0 \text { if } B, W \text { are independent Brownian Motions }  \tag{63}\\
& \int_{0}^{t} X_{t}\left(d B_{t}\right)^{2}=\int_{0}^{t} X_{t} d t \tag{64}
\end{align*}
$$

Symbolically this is commonly expressed as follows

$$
\begin{align*}
& d t^{2}=0  \tag{66}\\
& d B_{t} d t=0  \tag{67}\\
& d B_{t} d W_{t}=0  \tag{68}\\
& \left(d B_{t}\right)^{2}=d t \tag{69}
\end{align*}
$$

Sketch of proof:
Let $\pi=\left\{0=t_{0} \leq t_{1} \cdots \leq t_{n}=t\right\}$ a partition of the $[0, t]$ with equal intervals, i.e. $t_{k+1}-t_{k}=\Delta t$.

- Regarding $d t^{2}=0$ note

$$
\begin{equation*}
\lim _{\Delta_{t} \rightarrow 0} \sum_{k=0}^{n-1} X_{t_{k}} \Delta t^{2}=\lim _{\Delta_{t} \rightarrow 0} \Delta_{t} \int_{0}^{t} X_{s} d s=0 \tag{70}
\end{equation*}
$$

- Regarding $d B_{t} d_{t}=0$ note

$$
\begin{equation*}
\lim _{\Delta_{t} \rightarrow 0} \sum_{k=0}^{n-1} X_{t_{k}} \Delta t \Delta B_{k}=\lim _{\Delta_{t} \rightarrow 0} \Delta_{t} \int_{0}^{t} X_{s} d B_{s}=0 \tag{71}
\end{equation*}
$$

- Regarding $d B_{t}^{2}=d t$ note

$$
\begin{align*}
& \mathbb{E}\left[\left(\sum_{k=0}^{n-1} X_{t_{k}} \Delta B_{k}^{2}-\sum_{k=0}^{n-1} X_{t_{k}} \Delta t\right)^{2}\right]=\mathbb{E}\left[\left(\sum_{k=0}^{n-1} X_{t_{k}}\left(\Delta B_{k}^{2}-\Delta t\right)\right)^{2}\right] \\
& \quad=\sum_{k=0}^{n-1} \sum_{k^{\prime}=0}^{n-1} \mathbb{E}\left[X_{t_{k}} X_{t_{k}^{\prime}}\left(\Delta B_{k}^{2}-\Delta t\right)\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)\right] \tag{72}
\end{align*}
$$

If $k>k^{\prime}$ then $\left(\Delta B_{k}^{2}-\Delta t\right)$ is independent of $X_{t_{k}} X_{t_{k^{\prime}}}\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)$, and therefore

$$
\begin{align*}
\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}}\right. & \left.\left(\Delta B_{k}^{2}-\Delta t\right)\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)\right] \\
& \left.=\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}}\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)\right] \mathbb{E}\left[\Delta B_{k}^{2}-\Delta t\right)\right]=0 \tag{73}
\end{align*}
$$

Equivalently, if $k^{\prime}>k$ then $\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)$ is independent of $X_{t_{k}} X_{t_{k^{\prime}}}\left(\Delta B_{k}^{2}-\right.$ $\Delta t)$ and therefore

$$
\begin{align*}
\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}}\right. & \left.\left(\Delta B_{k}^{2}-\Delta t\right)\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)\right] \\
& \left.=\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}}\left(\Delta B_{k}^{2}-\Delta t\right)\right] \mathbb{E}\left[\Delta B_{k^{\prime}}^{2}-\Delta t\right)\right]=0 \tag{74}
\end{align*}
$$

Thus

$$
\begin{equation*}
\sum_{k=0}^{n-1} \sum_{k^{\prime}=0}^{n-1} \mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}}\left(\Delta B_{k}^{2}-\Delta t\right)\left(\Delta B_{k^{\prime}}^{2}-\Delta t\right)\right]=\sum_{k=0}^{n-1} \mathbb{E}\left[X_{t_{k}}^{2}\left(\Delta B_{k}^{2}-\Delta t\right)^{2}\right] \tag{75}
\end{equation*}
$$

Note since $\Delta B_{k}$ is independent of $X_{t_{k}}$ then

$$
\begin{align*}
& \mathbb{E}\left[X_{t_{k}}^{2}\left(\Delta B_{k}^{2}-\Delta t\right)^{2}=\mathbb{E}\left[X_{t_{k}}^{2}\right] \mathbb{E}\left[\left(\Delta B_{k}^{2}-\Delta t\right)^{2}\right]\right.  \tag{76}\\
& \quad=\mathbb{E}\left[X_{t_{k}}^{2}\right] \operatorname{Var}\left(\Delta B_{k}^{2}\right)=2 \mathbb{E}\left[X_{t_{k}}^{2}\right] \Delta t^{2} \tag{77}
\end{align*}
$$

Thus

$$
\begin{equation*}
\mathbb{E}\left[\left(\sum_{k=0}^{n-1} X_{t_{k}} \Delta B_{k}^{2}-\sum_{k=0}^{n-1} X_{t_{k}} \Delta t\right)^{2}\right]=\sum_{k=0}^{n-1} \mathbb{E}\left[X_{t_{k}}^{2}\right] \Delta_{t}^{2} \tag{78}
\end{equation*}
$$

which goes to zero as $\Delta t \rightarrow 0$. Thus, in the limit as $\Delta t \rightarrow 0$

$$
\begin{equation*}
\lim _{\Delta t \rightarrow 0} \sum_{k=0}^{n-1} X_{t_{k}} \Delta B_{k}^{2}=\lim _{\Delta t \rightarrow 0} \sum_{k=0}^{n-1} X_{t_{k}} \Delta t \tag{79}
\end{equation*}
$$

where the limit is taken in the mean square sense. Thus

$$
\begin{equation*}
\int_{0}^{t} X_{s} d B_{s}^{2}=\int_{0}^{t} X_{s} d s \tag{80}
\end{equation*}
$$

- Regarding $d B_{t} d W_{t}=0$ note

$$
\begin{equation*}
\mathbb{E}\left[\left(\sum_{k=0}^{n-1} X_{t_{k}} \Delta B_{k} \Delta W_{k}\right)^{2}\right]=\sum_{k=0}^{n-1} \sum_{k^{\prime}=0}^{n-1} \mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}} \Delta B_{k} \Delta W_{k} \Delta B_{k^{\prime}} \Delta W_{k^{\prime}}\right] \tag{81}
\end{equation*}
$$

If $k>k^{\prime}$ then $\Delta B_{k}, \Delta W_{k}$ are independent of $X_{t_{k}} X_{t_{k^{\prime}}}, \Delta B_{k^{\prime}} \Delta W_{k^{\prime}}$ and therefore
$\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}} \Delta B_{k} \Delta W_{k} \Delta B_{k^{\prime}} \Delta W_{k^{\prime}}\right]=\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}} \Delta B_{k^{\prime}} \Delta W_{k^{\prime}}\right] \mathbb{E}\left[\Delta B_{k}\right] \mathbb{E}\left[\Delta W_{k}\right]=0$

Equivalently, if $k^{\prime}>k$ then $\Delta B_{k^{\prime}}, \Delta W_{k^{\prime}}$ are independent of $X_{t_{k}} X_{t_{k^{\prime}}} \Delta B_{k} \Delta W_{k}$ and therefore

$$
\begin{equation*}
\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}} \Delta B_{k} \Delta W_{k} \Delta B_{k^{\prime}} \Delta W_{k^{\prime}}\right]=\mathbb{E}\left[X_{t_{k}} X_{t_{k^{\prime}}} \Delta B_{k} \Delta W_{k}\right] \mathbb{E}\left[\Delta B_{k^{\prime}}\right] \mathbb{E}\left[\Delta W_{k^{\prime}}\right]=0 \tag{83}
\end{equation*}
$$

Finally, for $k=k^{\prime}, \Delta B_{k}, \Delta W_{k}$ and $X_{t_{k}}$ are independent, thus

$$
\begin{equation*}
\mathbb{E}\left[X_{t_{k}}^{2} \Delta B_{k}^{2} \Delta W_{k}^{2}\right]=\mathbb{E}\left[X_{t_{k}}^{2}\right] \mathbb{E}\left[\Delta B_{k}^{2}\right] \mathbb{E}\left[\Delta W_{k}^{2}\right]=\mathbb{E}\left[X_{t_{k}}^{2}\right] \Delta t^{2} \tag{84}
\end{equation*}
$$

Thus

$$
\begin{equation*}
\mathbb{E}\left[\left(\sum_{k=0}^{n-1} X_{t_{k}} \Delta B_{k} \Delta W_{k}\right)^{2}\right]=\sum_{k=0}^{n-1} \mathbb{E}\left[X_{t_{k}}^{2}\right] \Delta t^{2} \tag{85}
\end{equation*}
$$

which converges to 0 as $\Delta t \rightarrow 0$. Thus

$$
\begin{equation*}
\int_{0}^{t} X_{s} d B_{s} d W_{s}=0 \tag{86}
\end{equation*}
$$

### 4.2 Vector Stochastic Differential Equations

The form

$$
\begin{equation*}
d X_{t}=a\left(X_{t}\right) d t+c\left(X_{t}\right) d B_{t} \tag{87}
\end{equation*}
$$

is also used to represent mutlivariate equations. In this case $X_{t}$ represents an $n$ dimensional random vector, $B_{t}$ an $m$-dimensional vector of $m$ independent standard Brownian motions, and $c\left(X_{t}\right.$ is an $n \times m$ matrix. $a$ is commonly known as the drift vector and $b$ the dispersion matrix.

## 5 Ito's Rule

Let $X_{t}$ be governed by an SDE

$$
\begin{equation*}
d X_{t}=a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t} \tag{88}
\end{equation*}
$$

Let $Y_{t}=f\left(X_{t}, t\right)$. Ito's rule tells us that $Y_{t}$ is governed by the following SDE

$$
\begin{equation*}
d Y_{t} \stackrel{\text { def }}{=} \nabla_{t} f\left(t, X_{t}\right) d t+\nabla_{x} f(t, x)^{T} d X_{t}+\frac{1}{2} d X_{t}^{T} \nabla_{x}^{2} f\left(t, X_{t}\right) d X_{t} \tag{89}
\end{equation*}
$$

where

$$
\begin{align*}
& d B_{i, t} d B_{j, t} \stackrel{\text { def }}{=} \delta(i, j) d t  \tag{90}\\
& d X d t \stackrel{\text { def }}{=} 0  \tag{91}\\
& d t^{2} \stackrel{\text { def }}{=} 0 \tag{92}
\end{align*}
$$

Equivalently

$$
\begin{align*}
& d Y_{t}=\nabla_{t} f\left(X_{t}, t\right) d_{t}+\nabla_{x} f\left(X_{t}, t\right)^{T} a\left(X_{t}, t\right) d_{t}+\nabla_{x} f\left(X_{t}, t\right)^{T} c\left(X_{t}, t\right) d B_{t} \\
& \quad+\frac{1}{2} \operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right)\right) d t \tag{93}
\end{align*}
$$

where

$$
\begin{align*}
& \nabla_{x} f(x, t)^{T} a(x, t)=\sum_{i} \frac{\partial f(x, t)}{\partial x_{i}} a_{i}(x, t)  \tag{94}\\
& \operatorname{trace}\left(c(x, t) c(x, t)^{T} \nabla_{x}^{2} f(x, t)\right)=\sum_{i} \sum_{j}\left(c(x, t) c(x, t)^{T}\right)_{i j} \frac{\partial^{2} f(x, t)}{\partial x_{i} \partial x_{j}} \tag{95}
\end{align*}
$$

Note $b$ is a matrix. Sketch of Proof: To second order

$$
\begin{align*}
\Delta Y_{t} & =f\left(X_{t+\Delta_{t}}, t+\Delta t\right)-f\left(X_{t}, t\right)=\nabla_{t} f\left(X_{t}, t\right) \Delta t+\nabla_{x} f\left(X_{t}, t\right)^{T} \Delta X_{t} \\
& +\frac{1}{2} \Delta t^{2} \nabla_{t}^{2} f\left(X_{t}, t\right)+\frac{1}{2} \Delta X_{t}^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) \Delta X_{t}+\Delta t\left(\nabla_{x} \nabla_{t} f\left(X_{t}, t\right)\right)^{T} \Delta X_{t} \Delta t \tag{96}
\end{align*}
$$

where $\nabla_{t}, \nabla_{x}$ are the gradients with respect to time and state, and $\nabla_{t}^{2}$ is the second derivative with respect to time, $\nabla_{x}^{2}$ the Hessian with respect to time and $\nabla_{x} \nabla_{t}$ the
gradient with respect to state of the gradient with respect to time. Integrating over time

$$
\begin{equation*}
Y_{t}=Y_{0}+\sum_{k=0^{\prime}}^{n-1} \Delta Y_{t_{k}} \tag{97}
\end{equation*}
$$

and taking limits

$$
\begin{align*}
Y_{t}= & Y_{0}+\int_{0}^{t} d Y_{s}=Y_{0}+\int_{0}^{t} \nabla_{t} f\left(X_{s}, s\right) d_{s}+\int_{0}^{t} \nabla_{x} f\left(X_{s}, s\right)^{T} d X_{s} \\
& +\frac{1}{2} \int_{0}^{t} \nabla_{t}^{2} f\left(X_{s}, s\right)(d s)^{2}+\frac{1}{2} \int_{0}^{t} d X_{s}^{T} \nabla_{x}^{2} f\left(X_{s}, s\right) d X_{s} \\
& +\int_{0}^{t}\left(\nabla_{x} \nabla_{t} f\left(X_{s}, s\right)\right)^{T} d X_{s} d s \tag{98}
\end{align*}
$$

In differential form

$$
\begin{align*}
d Y_{t}= & \nabla_{t} f\left(X_{t}, t\right) d_{t}+\nabla_{x} f\left(X_{t}, t\right)^{T} d X_{t} \\
& +\frac{1}{2} \nabla_{t}^{2} f\left(X_{t}, t\right)(d t)^{2}+\frac{1}{2} d X_{t}^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) d X_{t} \\
& +\left(\nabla_{x} \nabla_{t} f\left(X_{t}, t\right)\right)^{T} d X_{t} d t \tag{99}
\end{align*}
$$

Expanding $d X_{t}$

$$
\begin{align*}
\left(\nabla_{x} \nabla_{t} f\left(X_{t}, t\right)\right)^{T} d X_{t} d t & =\left(\nabla_{x} \nabla_{t} f\left(X_{t}, t\right)\right)^{T} a\left(X_{t}, t\right)(d t)^{2} \\
& +\left(\nabla_{x} \nabla_{t} f\left(X_{t}, t\right)\right)^{T} c\left(X_{t}, t\right) d B_{t} d t=0 \tag{100}
\end{align*}
$$

where we used the standard rules for second order differentials

$$
\begin{align*}
& (d t)^{2}=0  \tag{101}\\
& \left(d B_{t}\right) d t=0 \tag{102}
\end{align*}
$$

Moreover

$$
\begin{align*}
& d X_{t}^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) d X_{t} \\
& =\left(a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t}\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right)\left(a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t}\right) \\
& =a\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) a\left(X_{t}, t\right)(d t)^{2} \\
& +2 a\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) c\left(X_{t}, t\right)\left(d B_{t}\right) d t \\
& +d B_{t}^{T} c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) c\left(X_{t}, t\right)\left(d B_{t}\right) \tag{104}
\end{align*}
$$

Using the rules for second order differentials

$$
\begin{align*}
& (d t)^{2}=0  \tag{105}\\
& \left(d B_{t}\right) d t=0  \tag{106}\\
& d B_{t}^{T} K\left(X_{t}, t\right) d B_{t}=\sum_{i} \sum_{j} K_{i, j}\left(X_{t}, t\right) d B_{i, t} d B_{j, t}=\sum_{i} K_{i, i} d t \tag{107}
\end{align*}
$$

where

$$
\begin{equation*}
K\left(X_{t}, t\right)=c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) c\left(X_{t}, t\right) \tag{108}
\end{equation*}
$$

Thus

$$
\begin{align*}
d Y_{t}= & \nabla_{t} f\left(X_{t}, t\right) d_{t}+\nabla_{x} f\left(X_{t}, t\right)^{T} a\left(X_{t}, t\right) d t+\nabla_{x} f\left(X_{t}, t\right)^{T} c\left(X_{t}, t\right) d B_{t} \\
& +\frac{1}{2} \operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right)\right) d t \tag{109}
\end{align*}
$$

where we used the fact that

$$
\begin{align*}
\sum_{i} & K_{i i}\left(X_{t}, t\right) d t=\operatorname{trace}(K) d t \\
& =\operatorname{trace}\left(c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right) c\left(X_{t}, t\right)\right) \\
& =\operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right)\right) \tag{110}
\end{align*}
$$

### 5.1 Product Rule

Let $X, Y$ be Ito processes then

$$
\begin{equation*}
d\left(X_{t} Y_{t}\right)=X_{t} d Y_{t}+Y_{t} d X_{t}+d X_{t} d Y_{t} \tag{111}
\end{equation*}
$$

Proof: Consider $X, Y$ as a joint Ito process and take $f(x, y, t)=x y$. Then

$$
\begin{align*}
& \frac{\partial f}{\partial t}=0  \tag{112}\\
& \frac{\partial f}{\partial x}=y  \tag{113}\\
& \frac{\partial f}{\partial y}=x  \tag{114}\\
& \frac{\partial^{2} f}{\partial x \partial y}=1  \tag{115}\\
& \frac{\partial^{2} f}{\partial x^{2}}=\frac{\partial^{2} f}{\partial y^{2}}=0 \tag{116}
\end{align*}
$$

Applying Ito's rule, the Product Rule follows.
Exercise: Solve $\int_{0}^{T} B_{t} d B_{t}$ symbolically.
Let $a\left(X_{t}, t\right)=0, c\left(X_{t}, t\right)=1, f(x, t)=x^{2}$. Thus

$$
\begin{array}{r}
d X_{t}=d B_{t} \\
X_{t}=B_{t} \tag{118}
\end{array}
$$

and

$$
\begin{align*}
\frac{\partial f(t, x)}{\partial t} & =0  \tag{119}\\
\frac{\partial f(t, x)}{\partial x} & =2 x  \tag{120}\\
\frac{\partial^{2} f(t, x)}{\partial x^{2}} & =2 \tag{121}
\end{align*}
$$

Apllying Ito's rule

$$
\begin{align*}
d f\left(X_{t}, t\right)= & \frac{\partial f\left(X_{t}, t\right)}{\partial t} d t+\frac{\partial f\left(X_{t}, t\right)}{\partial x} a\left(X_{t}, t\right) d t+\frac{\partial f\left(X_{t}, t\right)}{\partial x} c\left(X_{t}, t\right) d B_{t} \\
& +\frac{1}{2} \operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \frac{\partial^{2} f(x, t)}{\partial x^{2}}\right) \tag{122}
\end{align*}
$$

we get

$$
\begin{equation*}
d B_{t}^{2}=2 B_{t} d B_{t}+d t \tag{123}
\end{equation*}
$$

Equivalently

$$
\begin{align*}
& \int_{0}^{t} d B_{s}^{2}=2 \int_{0}^{t} B_{s} d B_{s}+\int_{0}^{t} d s  \tag{124}\\
& B_{t}^{2}=2 \int_{0}^{t} B_{s} d B_{s}+t \tag{125}
\end{align*}
$$

Therefore

$$
\begin{equation*}
\int_{0}^{t} B_{s} d B_{s}=\frac{1}{2} B_{t}^{2}-\frac{1}{2} t \tag{126}
\end{equation*}
$$

NOTE: $d B_{t}^{2}$ is different from $\left(d B_{t}\right)^{2}$.
Exercise: Get $\mathbb{E}\left[e^{\beta} B_{t}\right]$
Let Let $a\left(X_{t}, t\right)=0, c\left(X_{t}, t\right)=1$, i.e., $d X_{t}=d B_{t}$. Let $Y_{t}=f\left(X_{t}, t\right)=e^{\beta B_{t}}$, and $d X_{t}=d B_{t}$. Using Ito's rule

$$
\begin{array}{r}
d Y_{t}=\beta e^{\beta B_{t}} d B_{t}+\frac{1}{2} \beta^{2} e^{\beta B_{t}} d t \\
Y_{t}=Y_{0}+\beta \int_{0}^{t} e^{\beta B_{s}} d B_{s}+\frac{\beta^{2}}{2} \int_{0}^{t} e^{\beta B_{s}} d s \tag{128}
\end{array}
$$

Taking expected values

$$
\begin{equation*}
\mathbb{E}\left[Y_{t}\right]=\mathbb{E}\left[Y_{0}\right]+\frac{\beta^{2}}{2} \int_{0}^{t} \mathbb{E}\left[Y_{s}\right] d s \tag{129}
\end{equation*}
$$

where we used the fact that $\mathbb{E}\left[\int_{0}^{t} e^{\beta B_{s}} d B_{s}\right]=0$ because for any non anticipatory random variable $Y_{t}$, we know that $\mathbb{E}\left[\int_{0}^{t} Y_{s} d B_{s}\right]=0$. Thus

$$
\begin{equation*}
\frac{d \mathbb{E}\left[Y_{t}\right]}{d t}=\frac{\beta^{2}}{2} \mathbb{E}\left[Y_{t}\right] \tag{130}
\end{equation*}
$$

and since $\mathbb{E}\left[Y_{0}\right]=1$

$$
\begin{equation*}
\mathbb{E}\left[e^{\beta B_{t}}\right]=e^{\frac{\beta^{2}}{2} t} \tag{131}
\end{equation*}
$$

Exercise: Solve the following SDE

$$
\begin{equation*}
d X_{t}=\alpha X_{t} d t+\beta X_{t} d B_{t} \tag{132}
\end{equation*}
$$

In this case $a\left(X_{t}, t\right)=\alpha X_{t}, c\left(X_{t}, t\right)=\beta X_{t}$. Using Ito's formula for $f(x, t)=\log (x)$

$$
\begin{align*}
& \frac{\partial f(t, x)}{\partial t}=0  \tag{133}\\
& \frac{\partial f(t, x)}{\partial x}=\frac{1}{x}  \tag{134}\\
& \frac{\partial^{2} f(t, x)}{\partial x^{2}}=-\frac{1}{x^{2}} \tag{135}
\end{align*}
$$

Thus

$$
\begin{equation*}
d \log \left(X_{t}\right)=\frac{1}{X_{t}} \alpha X_{t} d t+\frac{1}{X_{t}} \beta X_{t} d B_{t}-\frac{1}{2 X_{t}^{2}} \beta^{2} X_{t}^{2} d t=\left(\alpha-\frac{\beta^{2}}{2}\right) d t+\beta d B_{t} \tag{136}
\end{equation*}
$$

Integrating over time

$$
\begin{align*}
& \log \left(X_{t}\right)=\log \left(X_{0}\right)+\left(\alpha-\frac{\beta^{2}}{2}\right) t+\beta B_{t}  \tag{137}\\
& X_{t}=X_{0} \exp \left(\left(\alpha-\frac{\beta^{2}}{2}\right) t\right) \exp \left(\beta B_{t}\right) \tag{138}
\end{align*}
$$

Note

$$
\begin{equation*}
\mathbb{E}\left[X_{t}\right]=\mathbb{E}\left[X_{0}\right] e^{\left(\alpha-\frac{\beta^{2}}{2}\right) t} \mathbb{E}\left[\exp \left(\alpha B_{t}\right)\right]=\mathbb{E}\left[X_{0}\right] e^{\alpha t} \tag{139}
\end{equation*}
$$

## 6 Generator of an Ito Diffusion

The generator $G_{t}$ of the Ito diffusion

$$
\begin{equation*}
d X_{t}=a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t} \tag{140}
\end{equation*}
$$

is a second order partial differential operator. For any funcion $f$ it provides the directional derivative of $f$ averaged accross the paths generated by the diffusion. In particular given the function $f$, the function $G_{t}[f]$ is defined as follows

$$
\begin{align*}
& G_{t}[f](x)=\frac{d \mathbb{E}\left[f\left(X_{t}\right) \mid X_{t}=x\right]}{d t}=\lim _{\Delta t \rightarrow 0} \frac{\mathbb{E}\left[f\left(X_{t+\Delta_{t}}\right) \mid X_{t}=x\right]-f(x)}{\Delta t} \\
& =\frac{\mathbb{E}\left[d f\left(X_{t}\right) \mid X_{t}=x\right]}{d t} \tag{141}
\end{align*}
$$

Note using Ito's rule

$$
\begin{align*}
d f\left(X_{t}\right)= & \nabla_{x} f\left(X_{t}, t\right)^{T} a\left(X_{t}, t\right) d t+\nabla_{x} c\left(X_{t}, t\right)^{T} d B_{t} \\
& +\frac{1}{2} \operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} f\left(X_{t}, t\right)\right) d t \tag{142}
\end{align*}
$$

Taking expected values

$$
\begin{equation*}
G_{t}[f](x)=\frac{\mathbb{E}\left[d f\left(X_{t}\right) \mid X_{t}=x\right]}{d t}=\nabla_{x} f(x)^{T} a(x, t)+\frac{1}{2} \operatorname{trace}\left(c(x, t) c(x, t)^{T} \nabla_{x}^{2} f(x)\right) \tag{143}
\end{equation*}
$$

In other words

$$
\begin{equation*}
G_{t}[\cdot]=\sum_{i} a_{i}(x, t) \frac{\partial}{\partial x_{i}}[\cdot]+\frac{1}{2} \sum_{i} \sum_{j}\left(c(x, t) c(x, t)^{T}\right)_{i, j} \frac{\partial^{2}}{\partial x_{i} \partial x_{j}}[\cdot] \tag{144}
\end{equation*}
$$

## 7 Adjoints

Every linear operator $G$ on a Hilbert space $H$ with inner product $<\cdot, \cdot>$ has a correspoinding adjoint operator $G^{*}$ such that

$$
\begin{equation*}
<G x, y>=<x, G^{*} y>\text { for all } x, y \in H \tag{145}
\end{equation*}
$$

In our case the elements of the Hilbert space are functions $f, g$ and the inner product will be of the form

$$
\begin{equation*}
<f, g>=\int f(x) \cdot g(x) d x \tag{146}
\end{equation*}
$$

Using partial integrations it can be shown that if

$$
\begin{equation*}
G[f](x)=\sum_{i} \frac{\partial f(x)}{\partial x_{i}} a_{i}(x, t)+\frac{1}{2} \operatorname{trace}\left(c(x, t) c(x, t)^{T} \nabla_{x}^{2} f(x)\right) \tag{147}
\end{equation*}
$$

then

$$
\begin{equation*}
G^{*}[f](x)=-\sum_{i} \frac{\partial}{\partial x_{i}}[f(x) a(x, t)]+\frac{1}{2} \sum_{i, j} \frac{\partial^{2}}{\partial x_{i} \partial x_{j}}\left[b_{i, j}(x, t) f(x)\right] \tag{149}
\end{equation*}
$$

NOTe: Confirm b or bsquare

## 8 The Feynman-Kac Formula (Terminal Condition Version)

Let $X$ be an Ito diffusion

$$
\begin{equation*}
d X_{t}=a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t} \tag{150}
\end{equation*}
$$

with generator $G_{t}$

$$
\begin{equation*}
G_{t}[v](x)=\sum_{i} a_{i}(x, t) \frac{\partial v(x, t)}{\partial x_{i}}+\frac{1}{2} \sum_{i} \sum_{j}\left(c(x, t) c(x, t)^{T}\right)_{i, j} \frac{\partial^{2} v(x, t)}{\partial x_{i} \partial x_{j}} \tag{151}
\end{equation*}
$$

Let $v$ be the solution to the following pde

$$
\begin{equation*}
-\frac{\partial v(x, t)}{\partial t}=G_{t}[v](x, t)-v(x, t) f(x, t) \tag{152}
\end{equation*}
$$

with a known terminal condition $v(x, T)$, and function $f$. It can be shown that the solution to the pde (152) is as follows

$$
\begin{equation*}
v(x, s)=\mathbb{E}\left[v\left(X_{T}, T\right) \exp \left(-\int_{s}^{T} f\left(X_{t}\right) d t\right) \mid X_{s}=x\right] \tag{153}
\end{equation*}
$$

We can think of $v\left(X_{T}, T\right)$ as a terminal reward and of $\int_{s}^{T} f\left(X_{t}\right) d t$ as a discount factor.
Informal Proof:
Let $s \leq t \leq T$ let $Y_{t}=v\left(X_{t}, t\right), Z_{t}=\exp \left(-\int_{s}^{t} f\left(X_{\tau}\right) d \tau\right), U_{t}=Y_{t} Z_{t}$. It can be shown (see Lemma below) that

$$
\begin{equation*}
d Z_{t}=-Z_{t} f\left(X_{t}\right) d t \tag{154}
\end{equation*}
$$

Usint Ito's product rule

$$
\begin{equation*}
d U_{t}=d\left(Y_{t} Z_{t}\right)=Z_{t} d Y_{t}+Y_{t} d Z_{t}+d Y_{t} d Z_{t} \tag{155}
\end{equation*}
$$

Since $d Z_{t}$ has a $d t$ term, it follows that $d Y_{t} d Z_{t}=0$. Thus

$$
\begin{equation*}
d U_{t}=Z_{t} d v\left(X_{t}, t\right)-v\left(X_{t}, t\right) Z_{t} f\left(X_{t}\right) d t \tag{156}
\end{equation*}
$$

Using Ito's rule on $d v$ we get

$$
\begin{align*}
d v\left(X_{t}, t\right)= & \nabla_{t} v\left(X_{t}, t\right) d t+\left(\nabla_{x} v\left(X_{t}, t\right)\right)^{T} a\left(X_{t}, t\right) d t+\left(\nabla_{x} v\left(X_{t}, t\right)\right)^{T} c\left(X_{t}, t\right) d B_{t} \\
& +\frac{1}{2} \operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} v\left(X_{t}, t\right)\right) d t \tag{157}
\end{align*}
$$

Thus

$$
\begin{align*}
d U_{t}= & Z_{t}\left[\nabla_{t} v\left(X_{t}, t\right)+\left(\nabla_{x} v\left(X_{t}, t\right)\right)^{T} a\left(X_{t}, t\right)\right. \\
& \left.+\frac{1}{2} \operatorname{trace}\left(c\left(X_{t}, t\right) c\left(X_{t}, t\right)^{T} \nabla_{x}^{2} v\left(X_{t}, t\right)\right)-v\left(X_{t}, t\right) f\left(X_{t}\right)\right] d t \\
& +Z_{t}\left(\nabla_{x} v\left(X_{t}, t\right)\right)^{T} c\left(X_{t}, t\right) d B_{t} \tag{158}
\end{align*}
$$

and since $v$ is the solution to (152) then

$$
\begin{equation*}
d U_{t}=\left(\nabla_{x} v\left(X_{t}, t\right)\right)^{T} c\left(X_{t}, t\right) d B_{t} \tag{159}
\end{equation*}
$$

Integrating

$$
\begin{equation*}
U_{T}-U_{s}=\int_{s}^{T} Y_{t}\left(\nabla_{x} v\left(X_{t}, t\right)\right)^{T} c\left(X_{t}, t\right) d B_{t} \tag{160}
\end{equation*}
$$

taking expected values

$$
\begin{equation*}
\mathbb{E}\left[U_{T} \mid X_{s}=x\right]-\mathbb{E}\left[U_{s} \mid X_{s}=x\right]=0 \tag{161}
\end{equation*}
$$

where we used the fact that the expected values of integrals with respect to Brownian motion is zero. Thus, since $U_{s}=Y_{0} Z_{0}=v\left(X_{s}, s\right)$

$$
\begin{equation*}
\mathbb{E}\left[U_{T} \mid X_{s}=x\right]=\mathbb{E}\left[U_{s} \mid X_{s}=x\right]=v(x, s) \tag{162}
\end{equation*}
$$

Using the definition of $U_{T}$ we get

$$
\begin{equation*}
v(x, s)=\mathbb{E}\left[v\left(X_{T}, T\right) e^{-\int_{s}^{T} f\left(X_{t}\right) d t} \mid X_{s}=x\right] \tag{163}
\end{equation*}
$$

We end the proof by showing that

$$
\begin{equation*}
d Z_{t}=-Z_{t} f\left(X_{t}\right) d t \tag{164}
\end{equation*}
$$

First let $Y_{t}=\int_{s}^{t} f\left(X_{\tau}\right) d \tau$ and note

$$
\begin{array}{r}
\Delta Y_{t}=\int_{t}^{t+\Delta_{t}} f\left(X_{\tau}\right) d \tau \approx f\left(X_{t}\right) \Delta t \\
d Y_{t}=f\left(X_{t}\right) d t \tag{166}
\end{array}
$$

Let $Z_{t}=\exp \left(-Y_{t}\right)$. Using Ito's rule

$$
\begin{equation*}
d Z_{t}=\nabla e^{-Y_{t}} d Y_{t}+\frac{1}{2} \nabla^{2} e^{-Y_{t}}\left(d Y_{t}\right)^{2}=-e^{-Y_{t}} f\left(X_{t}\right) d t=-Z_{t} f\left(X_{t}\right) d t \tag{167}
\end{equation*}
$$

where we used the fact that

$$
\begin{equation*}
\left(d Y_{t}\right)^{2}=Z_{t}^{2} f\left(X_{t}\right)^{2}(d t)^{2}=0 \tag{168}
\end{equation*}
$$

## 9 Kolmogorov Backward equation

The Kolmogorov backward equation tells us at time $s$ whether at a future time $t$ the system will be in the target set $A$. We let $\xi$ be the indicator function of $A$, i.e, $\xi(x)=1$ if $x \in A$, otherwise it is zero. We want to know for every state $x$ at time $s<T$ what is the probability of ending up in the target set $A$ at time $T$. This is call the the hit probablity.

Let $X$ be an Ito diffusion

$$
\begin{align*}
& d X_{t}=a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t}  \tag{169}\\
& X_{0}=x \tag{170}
\end{align*}
$$

The hit probability $p(x, t)$ satisfies the Kolmogorov backward pde

$$
\begin{equation*}
-\frac{\partial p(x, t)}{\partial t}=G_{t}[p](x, t) \tag{171}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
-\frac{\partial p(x, t)}{\partial t}=\sum_{i} a_{i}(x, t) \frac{\partial p(x, t)}{\partial x_{i}}+\frac{1}{2} \sum_{i, j}\left(c(x, t) c(x, t)^{T}\right)_{i j} \frac{\partial^{2} p(x, t)}{\partial x_{i} \partial x_{j}} \tag{172}
\end{equation*}
$$

subject to the final condition $p(x, T)=\xi(x)$. The equation can be derived from the Feynman-Kac formula, noting that the hit probability is an expected value over paths that originate at $x$ at time $s \leq T$, and setting $f(x)=0, q(x)=\xi(x)$ for all $x$

$$
\begin{equation*}
p(x, t)=p\left(X_{T} \in A \mid X_{t}=x\right]=\mathbb{E}\left[\xi\left(X_{T}\right) \mid X_{t}=x\right]=\mathbb{E}\left[q\left(X_{T}\right) e^{\int_{t}^{T} f\left(X_{s}\right) d s}\right] \tag{173}
\end{equation*}
$$

## 10 The Kolmogorov Forward equation

Let $X$ be an Ito diffusion

$$
\begin{align*}
& d X_{t}=a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t}  \tag{174}\\
& X_{0}=x_{0} \tag{175}
\end{align*}
$$

with generator $G$. Let $p(x, t)$ represent the probability density of $X_{t}$ evaluated at $x$ given the initial state $x_{0}$. Then

$$
\begin{equation*}
\frac{\partial p(x, t)}{\partial t}=G^{*}[p](x, t) \tag{176}
\end{equation*}
$$

where $G^{*}$ is the adjoint of $G$, i.e.,

$$
\begin{equation*}
\frac{\partial p(x, t)}{\partial t}=-\sum_{i} \frac{\partial}{\partial x_{i}}[p(x, t) a(x, t)]+\frac{1}{2} \sum_{i, j} \frac{\partial^{2}}{\partial x_{i} \partial x_{j}}\left[\left(c(x, t) c(x, t)^{T}\right)_{i j} p(x, t)\right] \tag{177}
\end{equation*}
$$

## 11 Girsanov's Theorem

Let $X$ a process defined by the following SDE

$$
\begin{equation*}
d X_{t}=a\left(X_{t}\right) d t+c\left(X_{t}\right) d B_{t} \tag{178}
\end{equation*}
$$

where $c(\cdot) c(\cdot)^{\prime}$ is an invertible matrix. Let

$$
\begin{equation*}
Z \stackrel{\text { def }}{=} \exp \left(\int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) d X_{t}-\frac{1}{2} \int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) a\left(X_{t}\right) d t\right) \tag{179}
\end{equation*}
$$

where

$$
\begin{equation*}
k\left(X_{t}\right) \stackrel{\text { def }}{=}\left(c\left(X_{t}\right) c\left(X_{t}\right)^{\prime}\right)^{-1} \tag{180}
\end{equation*}
$$

and $B$ is a Brownian process under the probability measure $P$. Let the probability measure $Q$ be defined as follows

$$
\begin{equation*}
\frac{d \mathbb{P}}{d \mathbb{Q}}=Z \tag{181}
\end{equation*}
$$

Then the process $X_{1: T}$ is Brownian under $Q$.
Heuristic Proof: For a given path $x$ the ratio of the probability density of $x$ under $P$ and $Q$ can be approximated as follows

$$
\begin{equation*}
\frac{d \mathbb{P}(x)}{d \mathbb{Q}(x)} \approx \prod_{k} \frac{p\left(x_{t_{k+1}}-x_{t_{k}} \mid x_{t_{k}}\right)}{q\left(x_{t_{k+1}}-x_{t_{k}} \mid x_{t_{k}}\right)} \tag{182}
\end{equation*}
$$

were $\pi=\left\{0=t_{0}<t_{1} \cdots<t_{n}=T\right\}$ is a partition of $[0, T]$ and

$$
\begin{align*}
p\left(x_{t_{k+1}} \mid x_{t_{k}}\right) & =\mathcal{G}\left(\Delta x_{t_{k}} \mid a\left(x_{t_{k}}\right) \Delta t_{k}, \Delta t_{k} k\left(x_{t}\right)^{-1}\right)  \tag{183}\\
q\left(x_{t_{k+1}} \mid x_{t_{k}}\right) & =\mathcal{G}\left(\Delta x_{t_{k}} \mid 0, \Delta t_{k} k\left(x_{t}\right)^{-1}\right) \tag{184}
\end{align*}
$$

where $g(\cdot, \mu, \sigma)$ is the multivariate Gaussian distribution with mean $\mu$ and covariance matrix $c$. Thus

$$
\begin{align*}
\log \frac{d \mathbb{P}(x)}{d \mathbb{Q}(x)} \approx & \sum_{k=0}^{n-1}-\frac{1}{2 \Delta t_{k}}\left(\left(\Delta x_{t_{k}}-a\left(x_{t_{k}}\right) \Delta t_{k}\right)^{\prime} k\left(x_{t}\right)\left(\Delta x_{t_{k}}-a\left(x_{t_{k}}\right) \Delta t_{k}\right)\right. \\
& \left.-\Delta x_{t_{k}}^{\prime} k\left(x_{t}\right) \Delta x_{t_{k}}\right) \\
= & \sum_{k=0}^{n-1} a\left(x_{t_{k}}\right)^{\prime} k\left(x_{t}\right) \Delta x_{t_{k}}-\frac{1}{2} a\left(x_{t_{k}}\right)^{\prime} k\left(x_{t_{k}}\right) a\left(x_{t_{k}}\right) \Delta t_{k} \tag{185}
\end{align*}
$$

taking limits as $|\pi| \rightarrow 0$

$$
\begin{equation*}
\log \frac{d \mathbb{P}(x)}{d \mathbb{Q}(x)}=\int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) d X_{t}-\frac{1}{2} \int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) a\left(X_{t}\right) d t \tag{186}
\end{equation*}
$$

## Notes

$$
\begin{align*}
\frac{d \mathbb{P}}{d \mathbb{Q}} & =\exp \left(\int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) d X_{t}-\frac{1}{2} \int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) a\left(X_{t}\right) d t\right) \\
& =\exp \left(\int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right)\left(a\left(X_{t}, t\right) d t+c\left(X_{t}, t\right) d B_{t}\right)-\frac{1}{2} \int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) a\left(X_{t}\right) d t\right) \\
& =\exp \left(\int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) c\left(X_{t}, t\right) d B_{t}+\frac{1}{2} \int_{0}^{T} a\left(X_{t}\right)^{\prime} k\left(X_{t}\right) a\left(X_{t}\right) d t\right) \tag{187}
\end{align*}
$$

And if $c\left(X_{t}\right)$ is invertible $k\left(X_{t}\right) c\left(X_{t}\right)=c\left(X_{t}\right)^{-1}$ and

$$
\begin{equation*}
\frac{d \mathbb{P}}{d \mathbb{Q}}=\exp \left(\int_{0}^{T} a\left(X_{t}\right)^{\prime} c^{-1}\left(X_{t}, t\right) d B_{t}+\frac{1}{2} \int_{0}^{T}\left\|a\left(X_{t}\right)^{\prime} c^{-1}\left(X_{t}\right)\right\|^{2} d t\right) \tag{188}
\end{equation*}
$$

This form is popular in some textbooks.

## 12 Solving Stochastic Differential Equations

$$
\begin{equation*}
\text { Let } d X_{t}=a\left(t, X_{t}\right) d t+c\left(t, X_{t}\right) d B_{t} . \tag{189}
\end{equation*}
$$

Conceptually, this is related to $\frac{d X_{t}}{d t}=a\left(t, X_{t}\right)+c\left(t, X_{t}\right) \frac{d B_{t}}{d t}$ where $\frac{d B_{t}}{d t}$ is white noise. However, $\frac{d B_{t}}{d t}$ does not exist in the usual sense, since Brownian motion is nowhere differentiable with probability one.

We interpret solving for (189), as finding a process $X_{t}$ that satisfies

$$
\begin{equation*}
X_{t}=M+\int_{0}^{t} a\left(s, X_{s}\right) d s+\int_{0}^{t} c\left(s, X_{s}\right) d B s \tag{190}
\end{equation*}
$$

for a given standard Brownian process $B$. Here $X_{t}$ is an Ito process with $a\left(s, X_{s}\right)=$ $K_{s}$ and $c\left(s, X_{s}\right)=H_{s}$.
$a\left(t, X_{t}\right)$ is called the drift function.
$c\left(t, X_{t}\right)$ is called the dispersion function (also called diffusion or volatility function). Setting $b=0$ gives an ordinary differential equation.

## Example 1: Geometric Brownian Motion

$$
\begin{align*}
& d X_{t}=a X_{t} d t+b X_{t} d B_{t}  \tag{191}\\
& X_{0}=\xi>0 \tag{192}
\end{align*}
$$

Using Ito's rule on $\log X_{t}$ we get

$$
\begin{align*}
d \log X_{t} & =\frac{1}{X_{t}} d X_{t}+\frac{1}{2}\left(-\frac{1}{X_{t}^{2}}\right)^{2}\left(d X_{t}\right)^{2}  \tag{193}\\
& =\frac{d X_{t}}{X_{t}}-\frac{1}{2} b^{2} d t  \tag{194}\\
& =\left(a X_{t}-\frac{1}{2} b^{2}\right) d t+\alpha d B_{t} \tag{195}
\end{align*}
$$

Thus

$$
\begin{equation*}
\log X_{t}=\log X_{0}+\left(a-\frac{1}{2} b^{2}\right) t+b B_{t} \tag{196}
\end{equation*}
$$

and

$$
\begin{equation*}
X_{t}=X_{0} e^{\left(a-\frac{1}{2} b^{2}\right) t+b B_{t}} \tag{197}
\end{equation*}
$$

Processes of the form

$$
\begin{equation*}
Y_{t}=Y_{0} e^{\alpha t+\beta B_{t}} \tag{198}
\end{equation*}
$$

where $\alpha$ and $\beta$ are constant, are called Geometric Brownian Motions. Geometric Brownian motion $X_{t}$ is characterized by the fact that the log of the process is Brownian motion. Thus, at each point in time, the distribution of the process is log-normal.
Let's study the dynamics of the average path. First let

$$
\begin{equation*}
Y_{t}=e^{b B_{t}} \tag{199}
\end{equation*}
$$

Using Ito's rule

$$
\begin{align*}
& d Y_{t}=b e^{b B_{t}} d B_{t}+\frac{1}{2} b^{2} e^{b B_{t}}\left(d B_{t}\right)^{2}  \tag{200}\\
& Y_{t}=Y_{0}+b \int_{0}^{t} Y_{s} d B_{s}+\frac{1}{2} b^{2} \int+0^{t} Y_{s} d s  \tag{201}\\
& \mathbb{E}\left(Y_{t}\right)=\mathbb{E}\left(Y_{0}\right)+\frac{1}{2} b^{2} \int_{0}^{t} \mathbb{E}\left(Y_{s}\right) d s  \tag{202}\\
& \frac{d \mathbb{E}\left(Y_{t}\right)}{d_{t}}=\frac{1}{2} b^{2} \mathbb{E}\left(Y_{t}\right)  \tag{203}\\
& \mathbb{E}\left(Y_{t}\right)=\mathbb{E}\left(Y_{0}\right) e^{\frac{1}{2} b^{2} t}=e^{\frac{1}{2} b^{2} t} \tag{204}
\end{align*}
$$

Thus

$$
\begin{equation*}
\mathbb{E}\left(X_{t}\right)=\mathbb{E}\left(X_{0}\right) e^{\left(a-\frac{1}{2} b^{2}\right) t} \mathbb{E}\left(Y_{t}\right)=\mathbb{E}\left(X_{0}\right) e^{\left(a-\frac{1}{2} b^{2}\right) t} \tag{205}
\end{equation*}
$$

Thus the average path has the same dynamics as the noiseless system. Note the result above is somewhat trivial considering

$$
\begin{equation*}
\mathbb{E}\left(d X_{t}\right)=d \mathbb{E}\left(X_{t}\right)=\mathbb{E}\left(a\left(X_{t}\right)\right) d t+\mathbb{E}\left(c\left(X_{t}\right) d B_{t}\right)=\mathbb{E}\left(a\left(X_{t}\right)\right) d t+\mathbb{E}\left(c\left(X_{t}\right)\right) \mathbb{E}\left(d B_{t}\right) \tag{206}
\end{equation*}
$$

$d \mathbb{E}\left(X_{t}\right)=\mathbb{E}\left(a\left(X_{t}\right)\right) d t$
and in the linear case

$$
\begin{equation*}
\left.\mathbb{E}\left(a\left(X_{t}\right)\right) d t=\mathbb{E}\left(a_{t} X_{t}+u_{t}\right) d t=a_{t} \mathbb{E}\left(X_{t}\right)+u_{t}\right) d t \tag{209}
\end{equation*}
$$

These symbolic operations on differentials trace back to the corresponding integral operations they refer to.

## 13 Linear SDEs

### 13.1 The Deterministic Case (Linear ODEs)

Let $x_{t} \in \Re^{n}$ be defined by the following ode

$$
\begin{align*}
& \frac{d x_{t}}{d t}=a_{t} x_{t}+u_{t}  \tag{210}\\
& x_{o}=\xi \tag{211}
\end{align*}
$$

where $u_{t}$ is known as the driving, or input, signal. The solution takes the following form:

$$
\begin{equation*}
x_{t}=\Phi_{t}\left(x_{0}+\int_{0}^{t} \Phi_{s}^{-1} u_{s} d s\right) \tag{212}
\end{equation*}
$$

where $\Phi_{t}$ is an $n \times n$ matrix, known as the fundamental solution, defined by the following ODE

$$
\begin{align*}
& \frac{d \Phi_{t}}{d t}=a_{t} \Phi_{t}  \tag{213}\\
& \Phi_{0}=I_{n} \tag{214}
\end{align*}
$$

Example: Let $x_{t}$ be a scalar such that

$$
\begin{equation*}
\frac{d x_{t}}{d t}=\alpha\left(x_{t}-u_{t}\right) \tag{215}
\end{equation*}
$$

Thus

$$
\begin{align*}
& \Phi_{t}=e^{-\alpha t}  \tag{216}\\
& x_{t}=e^{-t} x_{0}+\left(1-e^{-\alpha t}\right) u \tag{217}
\end{align*}
$$

### 13.2 The Stochastic Case

Linear SDEs have the following form

$$
\begin{align*}
& d X_{t}=\left(a_{t} X_{t}+u_{t}\right) d t+\sum_{i=1}^{m}\left(c_{i, t} X_{t}+v_{i, t}\right) d B_{i, t}  \tag{218}\\
& =\left(a_{t} X_{t}+u_{t}\right) d t+v_{t} d B_{t}+\sum_{i=1}^{m} c_{i, t} X_{t} d B_{i, t}  \tag{219}\\
& X_{0}=\xi \tag{220}
\end{align*}
$$

where $X_{t}$ is an $n$ dimensional random vector, $B_{t}=\left(B_{1}, \cdots, B_{m}\right), b_{i, t}$ are $n \times n$ matrices, and $v_{i, t}$ are the n-dimensional column vectors of the $n \times m$ matrix $v_{t}$. If $b_{i, t} t=0$ for all $i, t$ we say that the SDE is linear in the narrow sense. If $v_{t}=0$ for all $t$ we say that the SDE is homogeneous. The solution has the following form

$$
\begin{equation*}
X_{t}=\Phi_{t}\left(X_{0}+\int_{0}^{t} \Phi_{s}^{-1}\left(u_{s}-\sum_{i=1}^{m} b_{i, s} v_{i, s}\right) d s+\int_{0}^{t} \Phi_{s}^{-1} \sum_{i=1}^{m} v_{i, s} d B_{i, s}\right) \tag{221}
\end{equation*}
$$

where $\Phi_{t}$ is an $n \times n$ matrix satisfying the following matrix differential equation

$$
\begin{align*}
& d \Phi_{t}=a_{t} \Phi_{t} d t+\sum_{i=1}^{m} b_{i, s} \Phi_{s} d B_{i, s}  \tag{222}\\
& \Phi_{0}=I_{n} \tag{223}
\end{align*}
$$

One property of the linear Ito SDEs is that the trajectory of the expected value equals the trajectory of the associated deterministic system with zero noise. This is due to the fact that in the Ito integral the integrand is independent of the integrator $d B_{t}$ :

$$
\begin{equation*}
\mathbb{E}\left(d X_{t}\right)=d \mathbb{E}\left(X_{t}\right)=\mathbb{E}\left(a\left(X_{t}\right)\right) d t+\mathbb{E}\left(c\left(X_{t}\right) d B_{t}\right)=\mathbb{E}\left(a\left(X_{t}\right)\right) d t+\mathbb{E}\left(c\left(X_{t}\right)\right) \mathbb{E}\left(d B_{t}\right) \tag{224}
\end{equation*}
$$

$$
\begin{equation*}
d \mathbb{E}\left(X_{t}\right)=\mathbb{E}\left(a\left(X_{t}\right)\right) d t \tag{225}
\end{equation*}
$$

and in the linear case

$$
\begin{equation*}
\mathbb{E}\left(a\left(X_{t}\right)\right) d t=\mathbb{E}\left(a_{t} X_{t}+u_{t}\right) d t=a_{t}\left(\mathbb{E}\left(X_{t}\right)+u_{t}\right) d t \tag{227}
\end{equation*}
$$

### 13.3 Solution to the Linear-in-Narrow-Sense SDEs

In this case

$$
\begin{align*}
& d X_{t}=\left(a_{t} X_{t}+u_{t}\right) d t+v_{t} d B_{t}  \tag{228}\\
& X_{0}=\xi \tag{229}
\end{align*}
$$

where $v_{1}, \cdots, v_{m}$ are the columns of the $n \times m$ matrix $v$, and $d B_{t}$ is an m-dimensional Brownian motion. In this case the solution has the following form

$$
\begin{equation*}
X_{t}=\Phi_{t}\left(X_{0}+\int_{0}^{t} \Phi_{s}^{-1} u_{s} d s+\int_{0}^{t} \Phi_{s}^{-1} v_{s} d B_{s}\right) \tag{230}
\end{equation*}
$$

where $\Phi$ is defined as in the ODE case

$$
\begin{align*}
& \frac{d \Phi_{t}}{d t}=a_{t}  \tag{231}\\
& \Phi_{0}=I_{n} \tag{232}
\end{align*}
$$

White Noise Interpretation This solution can be interpreted using a "symbolic" view of white noise as

$$
\begin{equation*}
W_{t}=\frac{d B_{t}}{d_{t}} \tag{233}
\end{equation*}
$$

and thinking of the SDE as an ordinary $O D E$ with a driving term given by $u_{t}+v_{t} W_{t}$. We will see later that this interpretation breaks down for the more general linear case with $b_{t} \neq 0$.

Moment Equations Let

$$
\begin{align*}
& \rho_{r, s} \stackrel{\text { def }}{=} E\left(\left(X_{r}-m_{r}\right)\left(X_{s}-m_{s}\right)\right)  \tag{234}\\
& \rho_{t}^{2} \stackrel{\text { def }}{=} \rho_{t, t}=\operatorname{Var}\left(X_{t}\right) \tag{235}
\end{align*}
$$

Then

$$
\begin{align*}
& \frac{d \mathbb{E}\left(X_{t}\right)}{d t}=a_{t} d \mathbb{E}\left(X_{t}\right)+u_{t}  \tag{236}\\
& \mathbb{E}\left(X_{t}\right)=\Phi_{t}\left(\mathbb{E}\left(X_{0}\right)+\int_{0}^{t} \Phi_{s}^{-1} u_{s} d s\right)  \tag{237}\\
& \rho_{t}^{2}=\Phi_{t}\left(\rho_{0}^{2}+\int_{0}^{t} \Phi_{s}^{-1} v_{s}\left(\Phi_{s}^{-1} v_{s}\right)^{T} d s\right) \Phi_{t}^{T}  \tag{238}\\
& \frac{d \rho_{t}^{2}}{d t}=a_{t} \rho_{t}^{2}+\rho_{t}^{2} a_{t}^{T}+v_{t} v^{T}  \tag{239}\\
& \rho_{r, s}=\Phi_{r}\left(\rho_{0}^{2}+\int_{0}^{r \wedge s} \Phi_{t}^{-1} v_{t}\left(\Phi_{t}^{-1} v_{t}\right)^{T} d t\right) \Phi_{s}^{T} \tag{240}
\end{align*}
$$

where $r \wedge s=\min \{r, s\}$. Note the mean evolves according to the equivalent ODE with no driving noise.

## Constant Coefficients:

$$
\begin{equation*}
d X_{t}=a X_{t}+u+v d B_{t} \tag{241}
\end{equation*}
$$

In this case

$$
\begin{align*}
& \Phi_{t}=e^{a t}  \tag{242}\\
& \mathbb{E}\left(X_{t}\right)=e^{a t}\left(\mathbb{E}\left(X_{0}\right)+\int_{0}^{t} e^{-a s} u d s\right)  \tag{243}\\
& \operatorname{Var}\left(X_{t}\right)=\rho_{t}^{2}=e^{a t}\left\{\rho_{0}^{2}+\int_{0}^{t} e^{-a s} v v^{T}\left(e^{-a s}\right)^{T} d s\right\}\left(e^{a t}\right)^{T} \tag{244}
\end{align*}
$$

## Example: Linear Boltzmann Machines (Multidimensional OU Process)

$$
\begin{equation*}
d X_{t}=\theta\left(\gamma-X_{t}\right) d t+\sqrt{2 \tau} d B_{t} \tag{245}
\end{equation*}
$$

where $\theta$ is symmetric and $\tau>0$. Thus in this case

$$
\begin{align*}
a & =-\theta  \tag{246}\\
u & =\theta \gamma  \tag{247}\\
\Phi_{t} & =e^{-t \theta} \tag{248}
\end{align*}
$$

and

$$
\begin{align*}
& X_{t}=e^{-t \theta}\left(X_{0}+\int_{0}^{t} e^{s \theta} d s \theta \gamma+\sqrt{2 \tau} \int_{0}^{t} e^{s \theta} d B_{s}\right)  \tag{249}\\
& =e^{-t \theta}\left(X_{0}+\theta^{-1}\left[e^{s \theta}\right]_{0}^{t} \theta \gamma+\sqrt{2 \tau} \int_{0}^{t} e^{s \theta} d B_{s}\right)  \tag{250}\\
& =e^{-t \theta}\left(X_{0}+\left(e^{t \theta}-I\right) \gamma+\sqrt{2 \tau} \int_{0}^{t} e^{-a s} d B_{s}\right) \tag{251}
\end{align*}
$$

Thus

$$
\begin{align*}
& \quad \mathbb{E}\left(X_{t}\right)=e^{-t \theta} \mathbb{E}\left(X_{0}\right)+\left(I-e^{-t \theta}\right) \gamma  \tag{252}\\
& \lim _{t \rightarrow \infty} \mathbb{E}\left(X_{t}\right)=\gamma  \tag{253}\\
& \operatorname{Var}\left(X_{t}\right)=\rho_{t}^{2}=e^{-t \theta}\left\{\rho_{0}^{2}+2 \tau \int_{0}^{t} e^{2 s \theta} d s\right\} e^{-t \theta}  \tag{254}\\
& =e^{-2 t \theta}\left\{\rho_{0}^{2}+2 \tau \frac{\theta^{-1}}{2}\left[e^{2 s \theta}\right]_{0}^{t}\right\}  \tag{255}\\
& =e^{-2 t s}\left\{\rho_{0}^{2}+\tau \theta^{-1}\left(e^{2 t \theta}-I\right)\right\}  \tag{256}\\
& =e^{-2 t \theta} \rho_{0}^{2}+\tau \theta^{-1}\left(I-e^{-2 t \theta}\right)  \tag{257}\\
& =\tau \theta^{-1}+e^{-2 t \theta}\left(\rho_{0}^{2}-\tau \theta^{-1}\right)  \tag{258}\\
& \lim _{t \rightarrow \infty} \operatorname{Var}\left(X_{t}\right)=\tau \theta^{-1} \tag{259}
\end{align*}
$$

where we used the fact that $a, e^{a t}$ are symmetric matrices, and $\int e^{a t} d t=a^{-1} e^{a t}$. If the distribution of $X_{0}$ is Gaussian, the distribution continues being Gaussian at all times.

Example: Harmonic Oscillator Let $X_{t}=\left(X_{1, t}, X_{2, t}\right)^{T}$ represent the location and velocity of an oscillator

$$
d X_{t}=a X_{t}+\binom{0}{b} d B_{t}=\left(\begin{array}{cc}
0 & 1  \tag{260}\\
-\alpha & -\beta
\end{array}\right) d X_{t}+\binom{0}{b} d B_{t}
$$

thus

$$
\begin{equation*}
X_{t}=e^{a t}\left(X_{0}+\int_{0}^{t} e^{-a s}\binom{0}{b} d B_{s}\right) \tag{261}
\end{equation*}
$$

### 13.4 Solution to the General Scalar Linear Case

Here we will sketch the proof for the general solution to the scalar linear case. We have $X_{t} \in R$ defined by the following SDE

$$
\begin{equation*}
d X_{t}=\left(a_{t} X_{t}+u_{t}\right) d t+\left(b_{t} X_{t}+v_{t}\right) d B_{t} \tag{262}
\end{equation*}
$$

In this case the solution takes the following form

$$
\begin{align*}
& X_{t}=\Phi_{t}\left(X_{0}+\int_{0}^{t} \Phi_{s}^{-1}\left(u_{s}-v_{s} b_{s}\right) d s+\int_{0}^{t} \Phi_{s}^{-1} v_{s} d B s\right)  \tag{263}\\
& d \Phi_{t}=a_{t} \Phi_{t} d t+b_{t} \Phi_{t} d B_{t}  \tag{264}\\
& \Phi_{0}=1 \tag{265}
\end{align*}
$$

## Sketch of the proof

- Use Ito's rule to show

$$
\begin{equation*}
d \Phi_{t}^{-1}=\left(b^{2}-a_{t}\right) \Phi_{t}^{-1} d t-b_{t} \Phi_{t}^{-1} d B_{t} \tag{266}
\end{equation*}
$$

- Use Ito's rule to show that if $Y_{1, t}, Y_{2, t}$ are scalar processes defined as follows

$$
\begin{equation*}
d Y_{1, t}=a_{1}\left(t, Y_{1, t}\right) d t+b_{1}\left(t, Y_{1, t}\right) d B_{t}, \quad \text { for } i=1,2 \tag{267}
\end{equation*}
$$

then

$$
\begin{equation*}
d\left(Y_{1, t} Y_{2, t}\right)=Y_{1, t} d Y_{2, t}+Y_{2, t} d Y_{1, t}+b_{1}\left(t, Y_{1, t}\right) b_{2}\left(t, Y_{2, t}\right) d t \tag{269}
\end{equation*}
$$

- Use the property above to show that

$$
\begin{equation*}
d\left(X_{t} \Phi_{t}^{-1}\right)=\Phi_{t}^{-1}\left(\left(u_{t}-v_{t} b_{t}\right) d t+v_{t} d B_{t}\right) \tag{270}
\end{equation*}
$$

- Integrate above to get (263)
- Use Ito's rule to get

$$
\begin{align*}
& d \log \Phi_{t}^{-1}=\left(\frac{1}{2} b_{t}^{2}-a_{t}\right) d_{t}-b_{t} d B_{t}  \tag{271}\\
& \log \Phi_{t}=-\log \Phi_{t}^{-1}=\int_{0}^{t}\left(a_{s}-\frac{1}{2} b_{s}\right) d s+\int_{0}^{t} b_{s} d B_{s} \tag{272}
\end{align*}
$$

White Noise Interpretation Does not Work The white noise interpretation of the general linear case would be

$$
\begin{align*}
d X_{t} & =\left(a_{t} X_{t}+u_{t}\right) d_{t}+\left(b_{t} X_{t}+v_{t}\right) W_{t} d t  \tag{273}\\
& =\left(a_{t}+b_{t} W_{t}\right) X_{t} d_{t}+\left(u_{t}+v_{t} W_{t}\right) d t \tag{274}
\end{align*}
$$

If we interpret this as an ODE with noisy driving terms and coefficients, we would have a solution of the form

$$
\begin{align*}
& X_{t}=\Phi_{t}\left(X_{0}+\int_{0}^{t} \Phi_{s}^{-1}\left(u_{s}+v_{t} W_{t}\right)\right) d t  \tag{275}\\
& =\Phi_{t}\left(X_{0}+\int_{0}^{t} \Phi_{s}^{-1}\left(u_{s}-v_{s} b_{s}\right) d s+\int_{0}^{t} \Phi_{s}^{-1} v_{s} d B s\right) \tag{276}
\end{align*}
$$

with

$$
\begin{align*}
& d \Phi_{t}=\left(a_{t}+b_{t} W_{t}\right) \Phi_{t} d t=a_{t} \Phi_{t} d t+b_{t} \Phi_{t} d B_{t}  \tag{278}\\
& \Phi_{0}=1 \tag{279}
\end{align*}
$$

The ODE solution to $\Phi$ would be of the form

$$
\begin{equation*}
\log \Phi_{t}=\int_{0}^{t}\left(a_{s}+b_{s} W_{s}\right) d s=\int_{0}^{t} a_{s} d s+\int_{0}^{t} b_{s} d B_{s} \tag{280}
\end{equation*}
$$

which differs from the Ito SDE solution in (272) by the term $-\int_{0}^{t} b_{s} d_{s} / 2$.

### 13.5 Solution to the General Vectorial Linear Case

Linear SDEs have the following form

$$
\begin{align*}
& d X_{t}=\left(a_{t} X_{t}+u_{t}\right) d t+\sum_{i=1}^{m}\left(b_{i, t} X_{t}+v_{i, t}\right) d B_{i, t}  \tag{281}\\
& =\left(a_{t} X_{t}+u_{t}\right) d t+v d B_{t}+\sum_{i=1}^{m} b_{i, t} X_{t} d B_{i, t}  \tag{282}\\
& X_{0}=\xi \tag{283}
\end{align*}
$$

where $X_{t}$ is an $n$ dimensional random vector, $B_{t}=\left(B_{1}, \cdots, B_{m}\right), b_{i, t}$ are $n \times n$ matrices, and $v_{i, t}$ are the n-dimensional column vectors of the $n \times m$ matrix $v_{t}$. The solution has the following form

$$
\begin{equation*}
X_{t}=\Phi_{t}\left(X_{0}+\int_{0}^{t} \Phi_{s}^{-1}\left(u_{s}-\sum_{i=1}^{m} b_{i, s} v_{i, s}\right) d s+\int_{0}^{t} \Phi_{s}^{-1} \sum_{i=1}^{m} v_{i, s} d B_{i, s}\right) \tag{284}
\end{equation*}
$$

where $\Phi_{t}$ is an $n \times n$ matrix satisfying the following matrix differential equation

$$
\begin{equation*}
d \Phi_{t}=a_{t} \Phi_{t} d t+\sum_{i=1}^{m} b_{i, s} \Phi_{s} d B_{i, s} \quad \Phi_{0}=I_{n} \tag{285}
\end{equation*}
$$

An explicit solution for $\Phi$ cannot be found in general even when $a, b_{i}$ are constant. However if in addition of being constant they pairwise commute, $a g_{i}=g_{i} a, g_{i} g_{j}=$ $g_{j} g_{i}$ for all $i, j$ then

$$
\begin{equation*}
\Phi_{t}=\exp \left\{\left(a-\frac{1}{2} \sum_{i=1}^{m} b_{i}^{2}\right) t+\sum_{i=1}^{m} b_{i} B_{i, t}\right\} \tag{286}
\end{equation*}
$$

Moment Equations Let $m_{t}=\mathbb{E}\left(X_{t}\right), s_{t}=\mathbb{E}\left(X_{t} X_{t}^{T}\right)$, then

$$
\begin{align*}
\frac{d m_{t}}{d t}= & a_{t} m_{t}+u_{t}  \tag{287}\\
\frac{d s_{t}}{d t}= & a_{t} s_{t}+s_{t} a_{t}^{T}+\sum_{i=1}^{m} b_{i, t} m_{t} b_{i, t}^{T}+u_{t} m_{t}^{T}+m_{t} u_{t}^{T}  \tag{288}\\
& +\sum_{i=1}^{m}\left(b_{i, t} m_{t} v_{i, t}^{T}+v_{i, t} m_{t}^{T} b_{i, t}^{T}+v_{i, t} v_{i, t}^{T}\right) \tag{289}
\end{align*}
$$

The first moment equation can be obtained by taking expected values on (281). Note it is equivalent to the differential equation one would obtain for the deterministic part of the original system.

For the second moment equation apply Ito's rule

$$
\begin{equation*}
d X_{t} X^{T}=X_{t} d X_{t}^{T}+\left(d X_{t}\right) X_{t}^{T}+\sum_{i=1}^{m}\left[\left(b_{i, t} X_{t}+v_{i, t}\right)\left(X_{t}^{T} b_{i, t}^{T}+v_{i, t}\right)\right] d t \tag{290}
\end{equation*}
$$

substitute the $d X_{t}$ for its value in (281) and take expected values.

## Example: Multidimensional Geometric Brownian Motion

$$
\begin{equation*}
d X_{i, t}=a_{i} X_{i, t} d t+X_{i, t} \sum_{j=1}^{n} b_{i, j} d B_{j, t} \tag{291}
\end{equation*}
$$

for $i=1, \cdots, n$. Using Ito's rule

$$
\begin{array}{r}
d \log X_{i, t}=\frac{d X_{i, t}}{X_{i, t}}+\frac{1}{2}\left({\frac{-1}{X_{i}, t}}^{2}\right)\left(d X_{i, t}\right)^{2}= \\
\left(a_{i}-\sum_{j} \frac{1}{2} b_{i, j}^{2}\right)+\sum_{j} b_{i, j} d B_{i, j} \tag{293}
\end{array}
$$

Thus

$$
\begin{gather*}
X_{i, t}=X_{i, 0} \exp \left\{\left(a_{i}-\frac{1}{2} \sum_{j=1}^{n} b_{i, j}^{2}\right) t+\sum_{j=1}^{n} b_{i, j} B_{j, t}\right\}  \tag{294}\\
\log X_{i, t}=\log \left(X_{i, 0}\right)+\left(a_{i}-\frac{1}{2} \sum_{j=1}^{n} b_{i, j}^{2}\right) t+\log \left(\sum_{j=1}^{n} b_{i, j} B_{j, t}\right) \tag{295}
\end{gather*}
$$

and thus $X_{i, t}$ has a log-normal distribution.

## 14 Important SDE Models

- Stock Prices: Exponential Brownian Motion with Drift

$$
\begin{equation*}
d X_{t}=a X_{t} d t+b X_{t} d B_{t} \tag{296}
\end{equation*}
$$

- Vasiceck( 1977) Interest rate model: OU Process

$$
\begin{equation*}
d X_{t}=\alpha\left(\theta-X_{t}\right) d t+b d B_{t} \tag{297}
\end{equation*}
$$

- Cox-ingersol-Ross (1985) Interest rate model

$$
\begin{equation*}
d X_{t}=\alpha\left(\theta-X_{t}\right) d t+b \sqrt{X_{t}} d B_{t} \tag{298}
\end{equation*}
$$

- Generalized Cox Ingersoll Ross Model for short term interest rate, proposed by Chan et al (1992).

$$
\begin{equation*}
d X_{t}=\left(\theta_{0}-\theta_{1} X_{t}\right) d t+\gamma X_{t}^{\Psi} d B_{t}, \text { for } \Psi, \gamma>0 \tag{299}
\end{equation*}
$$

Let

$$
\begin{equation*}
\tilde{X}_{s}=\frac{X_{s}^{1-\Psi}}{\gamma(1-\Psi)} \tag{300}
\end{equation*}
$$

Thus

$$
\begin{equation*}
d \tilde{X}_{s}=a\left(\tilde{X}_{s}\right) d s+d B_{s} \tag{301}
\end{equation*}
$$

where

$$
\begin{equation*}
a(x)=\frac{\left(\theta_{0}+\theta_{1} \hat{x}\right) \hat{x}^{-\Psi}}{\gamma}-\frac{\Psi \gamma}{2} \hat{x}^{\Psi-1} \tag{302}
\end{equation*}
$$

where

$$
\begin{equation*}
\hat{x}=(\gamma(1-\Psi) x)^{(1-\Psi)^{-1}} \tag{303}
\end{equation*}
$$

A special case is when $\Psi=0.5$. In this case the process increments are known to have a non-central chi-squared distribution (Cox, Ingersoll, Ross, 1985)

- Logistic Growth
- Model I

$$
\begin{equation*}
d X_{t}=a X_{t}\left(1-X_{t} / k\right) d_{t}+b X_{t} d B_{t} \tag{304}
\end{equation*}
$$

The solution is

$$
\begin{equation*}
X_{t}=\frac{X_{0} \exp \left\{\left(a-b^{2} / 2\right) t+b B_{t}\right\}}{1+\frac{X_{0}}{k} a \int_{0}^{t} \exp \left\{\left(a-b^{2} / 2\right) s+b B_{s}\right\} d s} \tag{305}
\end{equation*}
$$

- Model II

$$
\begin{equation*}
d X_{t}=a X_{t}\left(1-X_{t} / k\right) d_{t}+b X_{t}\left(1-X_{t} / k\right) d B_{t} \tag{306}
\end{equation*}
$$

- Model III

$$
\begin{equation*}
d X_{t}=r X_{t}\left(1-X_{t} / k\right) d_{t}-s r X_{t}^{2} d B_{t} \tag{307}
\end{equation*}
$$

In all the models $r$ is the Maltusian growth constant and $k$ the carrying capacity of the environment. In model II, $k$ is unattainable. In the other models $X_{t}$ can have arbitrarily large values with nonzero probability.

- Gompertz Growth

$$
\begin{equation*}
d X_{t}=\alpha X_{t} d_{t} r X_{t} \log \left(\frac{k}{X_{t}}\right) d_{t}+b X_{t} d B_{t} \tag{308}
\end{equation*}
$$

where $r$ is the Maltusian growth constant and $k$ the carrying capacity. For $\alpha=0$ we get the Skiadas version of the model, for $r=0$ we get the lognormal model. Using Ito's rule on $Y_{t}=e^{\beta t} \log X_{t}$ we can get expected value follows the following equation

$$
\begin{equation*}
\mathbb{E}\left(X_{t}\right)=\exp \left\{\log \left(x_{0}\right) e^{-r t}\right\} \exp \left\{\frac{\gamma}{r}\left(1-e^{-r t}\right)\right\} \exp \left\{\frac{b^{2}}{4 r}\left(1-e^{-2 r t}\right\}\right. \tag{309}
\end{equation*}
$$

where

$$
\begin{equation*}
\gamma=\alpha-\frac{b^{2}}{2} \tag{310}
\end{equation*}
$$

Something fishy in expected value formula. Try $\alpha=b=0$ !

## 15 Stratonovitch and Ito SDEs

Stochastic differential equations are convenient pointers to their corresponding stochastic integral equations. The two most popular stochastic integrals are the Ito and the Stratonovitch versions. The advantage of the Ito integral is that the integrand is independent of the integrator and thus the integral is a Martingale. The advantage of the Stratonovitch definition is that it does not require changing the rules of standard calculus. The Ito interpretation of

$$
\begin{equation*}
d X_{t}=f\left(t, X_{t}\right) d t+\sum_{j=1}^{m} g_{j}\left(t, X_{t}\right) d B_{j, t} \tag{311}
\end{equation*}
$$

is equivalent to the Stratonovitch equation

$$
\begin{equation*}
d X_{t}=\left(f\left(t, X_{t}\right) d t-\frac{1}{2} \sum_{i=1}^{m} \sum_{j=1}^{m}\left[\frac{\partial g_{i, j}}{\partial x_{i}} g_{i} j\right]\left(t, X_{t}\right)\right) d t+\sum_{j=1}^{m} g_{j}\left(t, X_{t}\right) d B_{j, t} \tag{312}
\end{equation*}
$$

and the Stratonovitch interpreation of

$$
\begin{equation*}
d X_{t}=f\left(t, X_{t}\right) d t+\sum_{j=1}^{m} g_{j}\left(t, X_{t}\right) d B_{j, t} \tag{313}
\end{equation*}
$$

is equivalent to the Ito equation

$$
\begin{equation*}
d X_{t}=\left(f\left(t, X_{t}\right) d t+\frac{1}{2} \sum_{i=1}^{m} \sum_{j=1}^{m}\left[\frac{\partial g_{i, j}}{\partial x_{i}} g_{i} j\right]\left(t, X_{t}\right)\right) d t+\sum_{j=1}^{m} g_{j}\left(t, X_{t}\right) d B_{j, t} \tag{314}
\end{equation*}
$$

## 16 SDEs and Diffusions

- Diffusions are rocesses governed by the Fokker-Planck-Kolmogorov equation.
- All Ito SDEs are diffusions, i.e., they follow the FPK equation.
- There are diffusions that are not Ito diffusions, i.e., they cannot be described by an Ito SDE. Example: diffusions with reflection boundaries.

## 17 Appendix I: Numerical methods

### 17.1 Simulating Brownian Motion

### 17.1.1 Infinitesimal "piecewise linear" path segments

Get $n$ independent standard Gaussian variables $\left\{Z_{1}, \cdots, Z_{n}\right\}$;
$\mathbb{E}\left(Z_{i}\right)=0 ; \quad \operatorname{Var}\left(Z_{i}\right)=1$. Define the stochastic process $\hat{B}$ as follows,

$$
\begin{align*}
& \hat{B}_{t_{0}}=0  \tag{315}\\
& \hat{B}_{t_{1}}=\hat{B}_{t_{0}}+\sqrt{t_{1}-t_{0}} Z_{1}  \tag{316}\\
& \quad \vdots  \tag{317}\\
& \hat{B}_{t_{k}}=\hat{B}_{t_{k-1}}+\sqrt{t_{k}-t_{k-1}} Z_{k} \tag{318}
\end{align*}
$$

Moreover,

$$
\begin{equation*}
\hat{B}_{t}=\hat{B}_{t_{k-1}} \text { for } t \in\left[t_{k-1}, t_{k}\right) \tag{319}
\end{equation*}
$$

This defines a continuous time process that converges in distribution to Brownian motion as $n \rightarrow \infty$.

### 17.1.2 Linear Interpolation

Same as above but linearly interpolating the starting points of path segments.

$$
\begin{equation*}
\hat{B}_{t}=\hat{B}_{t_{k-1}}+\left(t-t_{k}\right)\left(\hat{B}_{t_{k-1}}-\hat{B}_{t_{k}}\right) /\left(t_{k}-t_{k-1}\right) \text { for } t \in\left[t_{k-1}, t_{k}\right) \tag{320}
\end{equation*}
$$

Note this approach is non-causal, in that it looks into the future. I believe it is inconsistent with Ito's interpretation and converges to Stratonovitch solutions

### 17.1.3 Fourier sine synthesis

$\hat{B}_{t}(\omega)=\sum_{k=0}^{n-1} Z_{k}(\omega) \phi_{k}(t)$
where $Z_{k}(\omega)$ are same random variables as in previous approach, and $\phi_{k}(t)=$ $\frac{2 \sqrt{2 T}}{(2 k+1) R} \sin \left(\frac{(2 k+1) R t}{2 T}\right)$
As $n \rightarrow \infty \quad B$ converges to BM in distribution. Note this approach is non-causal, in that it looks into the future. I believe it is inconsistent with Ito's interpretation and converges to Stratonovitch solutions

### 17.2 Simulating SDEs

Our goal is to simulate

$$
\begin{equation*}
d X_{t}=a\left(X_{t}\right) d t+c\left(X_{t}\right) d B_{t}, \quad 0 \leq t \leq T X_{0}=\xi \tag{321}
\end{equation*}
$$

Order of Convergencce Let $0=t_{1}<t_{2} \cdots<t_{k}=T$
A method is said to have strong oder of convergence $\alpha$ if there is aconstant $K$ such that

$$
\begin{equation*}
\sup _{t_{k}} \mathbb{E}\left|X_{t_{k}}-\hat{X}_{k}\right|<K\left(\Delta_{t_{k}}\right)^{\alpha} \tag{322}
\end{equation*}
$$

A method is said to have week oder of convergence $\alpha$ if there is a constant $K$ such that

$$
\begin{equation*}
\sup _{t_{k}}\left|\mathbb{E}\left[X_{t_{k}}\right]-\mathbb{E}\left[\hat{X}_{k}\right]\right|<K\left(\Delta_{t_{k}}\right)^{\alpha} \tag{323}
\end{equation*}
$$

## Euler-Maruyama Method

$$
\begin{align*}
& \hat{X}_{k}=\hat{X}_{k-1}+a\left(\hat{X}_{k-1}\right)\left(t_{k}-t_{k-1}\right)+c\left(\hat{X}_{k-1}\right)\left(B_{k}-B_{k-1}\right)  \tag{324}\\
& B_{k}=B_{k-1}+\sqrt{t_{k}-t_{k-1}} Z_{k} \tag{325}
\end{align*}
$$

where $Z_{1}, \cdots, Z_{n}$ are independent standard Gaussian random variables.
The Euler-Maruyama method has strong convergence of order $\alpha=1 / 2$, which is poorer of the convergence for the Euler method in the deterministic case, which is order $\alpha=1$. The Euler-Maruyama method has week convergence of order $\alpha=1$.

Milstein's Higher Order Method: It is based on a higher order truncation of the Ito-Taylor expansion

$$
\begin{align*}
\hat{X}_{k}= & \hat{X}_{k-1}+a\left(\hat{X}_{k-1}\right)\left(t_{k}-t_{k-1}\right)+c\left(\hat{X}_{k-1}\right)\left(B_{k}-B_{k-1}\right)  \tag{326}\\
& +\frac{1}{2} c\left(X_{k-1}\right) b^{\prime}\left(X_{k-1}\right)\left(\left(B_{k}-B_{k-1}\right)^{2}-\left(t_{k}-t_{k-1}\right)\right.  \tag{327}\\
B_{k}= & B_{k-1}+\sqrt{t_{k}-t_{k-1}} Z_{k} \tag{328}
\end{align*}
$$

This method has strong convergence of order $\alpha=1$.

## 18 History

- The first version of this document, which was 17 pages long, was written by Javier R. Movellan in 1999.
- The document was made open source under the GNU Free Documentation License 1.1 on August 12 2002, as part of the Kolmogorov Project.
- October 9, 2003. Javier R. Movellan changed the license to GFDL 1.2 and included an endorsement section.
- March 8, 2004: Javier added Optimal Stochastic Control section based on Oksendals book.
- September 18, 2005: Javier. Some cleaning up of the Ito Rule Section. Got rid of the solving symbolically section.
- January 15, 2006: Javier added new stuff to the Ito rule. Added the Linear SDE sections. Added Boltzmann Machine Sections.
- January/Feb 2011. Major reorganization of the tutorial.
